The space allotted for the exhibit in the Palace of Agriculture is 16 by 45 ft., a total of 720 sq. ft., with a wall space nearly 40 ft. in length. The material as it was prepared was shipped to Washington, where provision was made for installing it with a view to determining the best arrangement and the best utilization of the space. This matter has been in charge of W. H. Evans, of this Office, who has also supervised the preparation of a large number of charts and the photograph exhibit. The latter includes about 750 selected photographs of station buildings, grounds, laboratories, apparatus, experimental plats, herds, and other features, in addition to a collection of photographs of the station directors and staff members. This photographic exhibit makes an excellent showing, and is much the finest collection of experiment station pictures ever brought together, illustrating nearly every phase of the station work and equipment. In nearly all cases, the negatives were sent to Washington, so that all the photographs might be printed and finished alike. This has resulted in a much more pleasing and artistic effect. The pictures are mounted in groups on sheets of heavy cardboard 22 by 28 in., each sheet and each individual picture being labeled by hand. They will be displayed in portfolios of 24 sheets each.

This collection of photographs alone would suffice to furnish a good conception of the American stations, but the object exhibit has not been neglected, for this appeals to the eye of the more casual observer. A series of root cages furnished by the North Dakota Station shows the formation of the roots of maize, wheat, flax, and brome grass; a number of excellent models of sweet potatoes, peppers, apples, and plums, exhibited by the Iowa and Minnesota stations, illustrate varietal differences; and an exhibit of saltbush from the California Station shows such species of Atriplex as have proved of value on strongly alkaline soils. The soil work is represented by an exhibit from the Division of Soils of this Department, consisting of electrical devices for determining the salt content, temperature, and moisture content of soils, and a series of samples illustrating the typical agricultural soils of the United States; 6 typical California soils, sent by the station in that State, with specimens showing the result of mechanical analyses of each type of soil, and Hilgard's soil elutriator for mechanical analysis.

A number of pieces of original apparatus for investigations in vegetable physiology are shown, including an auxanometer for experimental work on the rate of plant growth, and a simple apparatus for determining the rate of transpiration of plants, both designed by L. C. Corbett, of the West Virginia Station; and a centrifuge used to study the effect of gravity and centrifugal force upon germinating seeds, designed by J. C. Arthur, of the Indiana Station. An olive exhibit, furnished by the California Station, consists of a set of 50 samples of olive oils and more than 200 samples of olive pits used in the classification of varieties of olives; and a collection of mounted specimens of cotton from the Alabama Station shows 72 selected and cross-bred varieties. A collection of 100 weed seeds, by B. D. Halsted, and an insect cabinet, designed by C. W. Woodworth of the California Station, are the sole representatives in their respective classes.

Samples of a considerable number of animal and vegetable fats are exhibited by the Missouri Station, and a collection of chemically pure proteids separated from the seeds of various plants, by T. B. Osborne, of the Connecticut State Station, is of much interest on account of the rarity of these products. The latter station has also contributed a gas desiccator, designed by S. W. Johnson, for drying hydrogen gas used in moisture determination. Two forms of the silo are shown in model, the ordinary round silo and the stave silo. An apparatus for the rapid cooling of wines in their manufacture, designed by the California Station, is exhibited by that station; and a pressure apparatus for experiments with solutions under very high pressure, designed by B. H. Hite, is shown by the West Virginia Station. A detail model of the Atwater-Rosa respiration calorimeter and a full-sized bomb calorimeter will illustrate our progress in these lines. Ten models and 8 photographs show the effect of different kinds of rations on the production of lean and fat meat, as determined in experiments with cattle, sheep, and pigs at a number of stations.

The dairy exhibit surpasses in extent that in any other single line. It includes a series of cheese models, exhibited by the New York State Station, showing the effect of the fat content of the milk on the size of cheese produced, and a collection of 48 cultures of dairy bacteria, prepared by H. W. Conn, of the Connecticut Storrs Station. The original Babcock milk tester is shown, and two more modern forms of the apparatus for hand and power operation, together with a quite complete collection of the various forms of apparatus used in the Babcock test. The Scovell milk-sampling tube, Wisconsin curd test, Marshall rennet test, acid bottles, and other minor apparatus are also shown.

An interesting feature of the exhibit is the irrigation apparatus and models. These include a hydrophore, used to determine the amount of silt carried by water, a nilometer, used to measure the amount of water passing through streams, flumes, and ditches, a current meter, used in measuring the rate of flow, and a water register, all designed by Elwood Mead; specimens of sheet-steel irrigation pipe, used extensively in rough regions in place of ditches or flumes, and models of a Cippoletti weir, measuring flume, and a truss and flume over a canyon, exhibited by this Office. A small exhibit from the Hawaiian Experiment Station consists of samples of rocks, lavas, lava products, and soils, varieties of sugar cane, and samples of agricultural products such as coffee, rice, and sugar.

In addition to the above object exhibit there are a large number of charts and enlarged pictures showing in graphic form the results of experiment station work on a wide range of subjects, as diseases of plants, nematode worms, soil and alkali investigations, effect of fertilizers, crossing of fruits and vegetables, feeding experiments, digestion coefficients, cheese ripening, egg production, irrigation enterprises, etc. The charts, most of them colored, have been executed by an expert and are excellent. They will be largely shown in portfolios, and it is expected that an attendant will be present to exhibit and explain them.

A complete set of bound bulletins and reports of the experiment stations and of this Office is shown, which makes quite an imposing array of agricultural literature. This is supplemented by the card index of experiment station literature, containing 18,000 cards, and by a large collection of books published privately by experiment station workers. Press notices, posters, and miscellaneous publications of the stations are shown in portfolios.

A manual of the American experiment stations is in the hands of the printer and will be ready in time to be included as a part of the station exhibit. This volume gives the history, organization, equipment, and lines of work of the stations, their relations to various other agricultural institutions, and their place in the great movement for the improvement and advancement of agriculture. It is illustrated by upward of 300 photo-engravings.

It will be apparent that abundant material has been provided in the various forms to give a fairly adequate idea of the American stations, and to furnish food for much study for visitors especially interested.

ARTIFICIAL CHANGES OF PHYSICAL PROPERTIES OF SOILS.

EWALD WOLLNY, PH. D.,

Professor in the Technical High School at Munich.

In this paper, which is a continuation of previous articles[1] on the physical properties of soils and their importance in the growth of plants, the author considers more particularly what practical means may be employed to impart to cultivated soils the greatest possible productiveness. That the proper cultivation of the soil is of prime importance is shown by the fact that other factors important in plant growth, *e. g.*, the plant food supplied by manures, can exert their full power only when the mechanical condition of the soil is favorable. Uncultivated soils generally fail to produce maximum yields. The most favorable physical conditions exist in those soils which consist of a thorough mixture of the several principal ingredients. Thus, soils in which either finely divided (clayey) or coarsely divided (sandy) ingredients predominate are unfavorable to the production of crops without decided changes in their properties, while soils in which the ingredients are mixed in certain proportions (medium soils) are generally productive. It is well known, for instance, that a pure humus soil, mainly on account of its physical nature, is not favorable to plant growth, but may be rendered productive by admixture with a soil deficient in humus.

PROPERTIES OF SOILS AS INDICATING THE NATURE OF THE CULTIVATION REQUIRED.

It is evident that in studying the various ways of cultivating soil, not only cohesion and adhesion, but also friction of the soil with the tools and the weight of a unit-volume of the soil, must be considered. The force with which the particles of soil cling to each other (cohere) is of prime importance in connection with the cultivation of the soil, since the ease or difficulty with which tools, penetrate the soil, and hence the labor required to cultivate the soil, depends primarily upon it. This is borne out by the results of investigations already referred to in the Record.[2] The controlling influence of cohesion may be inferred from the fact that it is the main factor determining the differences between soils, although the other properties of soils should also be taken into account, since the resistance to be overcome in cultivation is always due in part to them. In general, it may be said that humus offers the least resistance to cultivation, clay the greatest, while sand stands between the two extremes.

---

[1] E. S. R., 4, pp. 528, 627; 6, pp. 761, 853, 948.

[2] E. S. R., 6, p. 769.

If it be asked what practical means should be used to reduce to a minimum the labor of working soils, we should recommend a suitable change in composition of the soil as the first step. Thus, for example, mixing clay with sand diminishes both cohesion and adhesion of the soil, and renders it more easy to cultivate. It is true that by this treatment both the weight and friction of clay are increased, but, as modifications of cohesion and adhesion are more far-reaching, the increase in weight and friction may be neglected.

The improvement of the tillable properties of soils may be most perfectly attained by an increase in the proportion of humus. The working of clayey soil is by this means rendered very much less laborious, because both cohesion and adhesion, and also the weight, are diminished in proportion to the amount of humus added. For sandy soils also an increase of humus is of advantage, as it reduces friction and decreases the weight. It thus appears that manuring with materials of organic origin (stable manure, vegetable matter, straw, and peat)[1] greatly increases the ease of cultivation, and at the same time influences most favorably the chemical properties of the soil in many different ways.[2] Nor should the fact be overlooked that increasing the humus content promotes the tendency of the soil to assume the "crumbly" structure, and by this means still further reduces the mechanical resistance to cultivation. Soils of crumbly structure are not only naturally more fertile, but are very much more easily worked than those having a separate grain structure. Whatever manipulations, therefore, promote the formation of the crumbly structure and tend to make such structure permanent are of great value in soil cultivation, inasmuch as they both heighten the fertility of the soil and lessen the labor required for its cultivation. This is especially true of compact, heavy soils. To obtain this crumbly structure and to preserve it, several fundamental principles must be observed. These may be summed up briefly as follows: (1) The soil must be plowed immediately after the crop has been gathered; (2) it must be plowed only when it contains a medium amount of water (about 40 per cent of that which the soil is capable of holding); (3) the furrows must be as narrow as possible, especially at the first plowing; (4) the land destined for tillage in spring should be exposed in roughly plowed condition to the action of frosts during the winter; and (5) the formation of aggregates in the soil should be promoted by means of proper fertilizers. For the latter purpose humus-forming manures (stable and vegetable manure) as well as calcium hydrate (freshly slaked lime) are especially valuable. Hurtful influences, on the other hand, are exerted by such fertilizers as contain carbonates of the alkalis and soluble phosphates, inasmuch as these when applied in considerable quantities cause the soil particles to pack closely together. The same is true of materials rich in chlorids and nitrates. These salts promote the formation of crumbly structure while they remain in the soil, but when they are washed out by the rain water, they leave the soil in a puddled condition. This happens more or less with all salts which are not fixed by the soil. This can be corrected only by a careful selection and application of measures calculated to increase and preserve the percentage of humus in the soil.

RELATIONS OF SOILS TO AIR.

From the standpoint of the agriculturist, the principal property of soils in their relation to air is permeability, for on it depends the supply of oxygen required both for normal decomposition of organic material and for the respiration of the roots. The smaller and more densely packed the soil particles, the more limited the supply of oxygen and the greater the necessity for attempting to regulate the permeability. This end is best attained by mixing a fine-grained soil with sand and by inducing a crumbly structure. If too great humidity of the soil is responsible for the lack of permeability, only thorough drainage can correct the defect. If the soil has been deprived of its permeability by washing during periods of extraordinarily heavy precipitation, the best remedies are harrowing and hoeing between the rows, and heaping up the soil around the plants. The latter is a most efficient means of increasing permeability of the soil.

RELATIONS OF SOILS TO WATER.

Excess of water, either temporary or permanent, is hurtful to plant growth to a greater or less extent. Such a condition is a result principally of heavy precipitation on soils of high water capacity. The damage is most marked in case of basin-shaped fields on which water from neighboring fields accumulates, or which have an impervious subsoil at such a depth that the soil is kept in a state of saturation. The means adopted to correct this state of affairs will depend upon whether there is a permanent or only temporary excess of water. If the excess of water remains permanently or for a long period, it can be removed only by underdrainage or by the construction of ditches. The physical structure of the soil, more particularly its permeability and water capacity, determines the amount of water that may be removed by this means. The efficiency of the method consequently varies widely in different localities. A blind adherence to common rules of drainage may in some cases reduce the water supply in the soil to a degree dangerous to plant growth. This is the case (1) in all soils of small water capacity and considerable permeability (coarse-grained, sandy soils), (2) in soils offering considerable facilities for evaporation (peat and bog earth), and (3) in all soils occupied by plants requiring considerable amounts of moisture in the upper soil layer (meadows, perennial forage plants).

Thus, while the methods noted are effective in removing the hurtful excess of water, they may bring about a condition of dryness which in most cases, especially where rain is rare, and in time of drought, is unfavorable to the growth of maximum crops. To do away with this difficulty, which militates against the best interests of rational tillage of land, such means of regulation ought to be adopted as will either cause the water to drain off more slowly, or allow of complete stoppage of all flow temporarily. The former can be attained only imperfectly, because in the end all the water not held by the soil is removed; in the latter case, however, with proper care the moisture may be thoroughly utilized in accordance with the nature of the soil and the requirements of crops. Drainage can not be controlled effectively with open ditches, but it may very readily be done in case of under drains by calculating the diameter of the drain pipe on the basis of the quantity of water that percolates through hard, heavy soil. According to the experiments of the author, this amounts to 0.0008 cubic meter; or 0.8 liter per second and hectare.[1] With this as a basis, and starting with the smallest feasible diameter of pipe (4 cm.), the drainage system may be so constructed that part of the moisture may be kept in the soil for a long time. This, however, hardly answers the purpose, since the humidity of the soil, especially during the period of plant growth, can not be fully controlled. Hence it is recommended that open ditches be provided with board dams, and drains with flood gates, by means of which the flow of water may be interrupted either partly or entirely, as the occasion may require. This method is simple and easily applied in all ordinary forms of drainage.

The higher portions of a dangerously moist field should be reserved for grains and hoed crops, while the lower parts are used for crops which possess a high power of evaporation (such as meadows). Even in this case, however, the plants will suffer if the moisture in the soil exceeds 70 to 80 per cent of saturation.

The temporary pools which form on very fine-grained soils during heavy rains must be removed either by direct withdrawal of the water (water-furrows), or by such means as will bring about a diminution of the water capacity; in other words, an increase in permeability or an increase of evaporation from the soil. In the first case effort must be directed principally toward producing a crumbly structure through cultivation and manuring, as suggested above, since by this means the water-holding capacity of the soil is reduced and percolation promoted. On extremely fine-grained soils (clay soils, black earth), which in their unmodified condition offer the greatest resistance to the passage of water and become thoroughly moist only with the greatest difficulty, this process is indispensable in order that the precipitation may be of any use at all to plants.[2] A favorable modification of the water capacity and penetrability of such soils may also be brought about by admixture of soils of opposite physical characteristics, as, for instance, coarser grained soil (sand). By this means stiff soils are rendered more easy to cultivate, and are more readily changed into a condition of separate grain structure.

[2] Ibid., 18 (1895), p. 441.

Enlarging the surface of evaporation, as is done in ridge and hill culture, is another means of preventing harmful accumulation of water in soils. By this means, also, a portion of the rain water is removed from the reach of the plants by flowing into the furrows between the rows.

Close planting also assists to some extent in reducing the moisture in the soil by increasing the amount of water drawn from the soil by the crop.

It is a mistake to allow wet soils to lie fallow, especially in wet seasons, because the conditions in fallow soils are much less favorable to evaporation than in cultivated soils. Allowing soils to lie fallow, however, is not harmful; on the contrary, it may be useful, if the soil during a previous long drought has become dry to a considerable depth.

Lack of moisture in a soil may be corrected either by direct application of water (irrigation) or by increasing the absorptive power of the soil. Irrigation is to be recommended in all cases in which the water supplied by precipitation is insufficient for the production of maximum crops. The point at which irrigation becomes necessary varies in different localities and is determined by the energy of evaporation, the water-holding power of the soil, and the distribution of precipitation. In the warmer climates we may assume, as a rule, that when precipitation is less than 24 to 28 in. irrigation is required for maximum crops while in colder localities in which evaporation is less rapid and crops smaller, on account of the low temperature, the limit may be placed at about 16 in.[1]

With regard to the treatment of soils which have little water capacity, great permeability, and favorable conditions for evaporation, the aim should be mainly to keep the ground water at a proper level, or, if this is not possible, to increase the water capacity of the soil. The latter may be accomplished by admixture of fine-grained, earthy materials (clay, loam, and marl), or by increasing the percentage of humus through liberal applications of manures of organic origin (stable manure, peat, etc.).[2] Another, though less effective, means is rolling the soil, provided it be followed at the beginning of dry weather, by harrowing, hoeing, etc., to reduce evaporation.[3]

For soils of small water capacity such operations as limit evaporation as far as possible are generally recommended. Too frequent plowing of the soil should be avoided, and plowed land should be harrowed as soon as dry weather sets in, to reduce the surface of evaporation as much as possible. If the soil becomes too hard, as may happen as a result of violent rains or of rolling, loosening of the surface (harrowing, hoeing) is of great advantage in reducing evaporation and thus retaining moisture in the soil.[1] Furthermore, hill or ridge culture is to be avoided, since in this case evaporation is greater than in level culture. Close planting should not be practiced for the same reason. Allowing the soil to lie fallow may result in the storage of moisture in the soil, but it is recommended only when the soil is dry to a considerable depth. Finally, mulching or covering the soil with a layer of dead vegetable matter (stable manure, straw, etc.) reduces evaporation from the soil for a time at least.

RELATION OF SOILS TO TEMPERATURE.

Keeping in mind the great influence directly and indirectly exerted by the temperature of the soil upon the growth of plants, the practical agriculturist will endeavor to find means to modify the temperature according to the necessities of the plants. In colder climates, naturally, efforts must be made to promote a rise in temperature, while in warmer regions it will often be necessary to proceed in the opposite direction. In what ways and to what extent the temperature of the soil may be influenced is briefly discussed below.

In the cultivation of plants which furnish products of high market value, such as vines, fruit trees, etc., and which require a rather high temperature, artificial changes in exposure or inclination (producing southwest, south, or southeast exposure, or inclining the plane of growth more directly toward the south) may be of considerable benefit, especially in cold climates. The method, however, will be productive of good results only when the soil contains sufficient moisture, because only in that case is the higher temperature beneficial and the increase in yield sufficient to justify the outlay required to make the change. This method need not be restricted to hilly lands but can be applied to level soils. Roof-like elevations may be constructed, with broad surfaces facing toward the south, and rather narrow exposures toward the north. The former may be planted to crops that require considerable warmth (vines, fruits, asparagus, etc.), and the latter may be reserved for grass or such other forage plants as require less heat. This method is not adapted to extensive field culture of crops furnishing products of comparatively low market value, both on account of the very unequal growth of the plants on the two opposite inclinations, and because the benefit derived even under favorable circumstances would not justify the outlay.

On hilly land in hot climates a reduction of the temperature of the soil may be necessary on steep inclinations facing toward the south, southeast, or southwest, because under such conditions, not taking into account the fact that the moisture is generally insufficient for maximum crops, the temperature of the soil frequently exceeds the limits for the perfect development of plants. In such cases the construction of terraces offers special advantages, since by their means the temperature of the soil may be lowered and the moisture in the soil regulated in accordance with the needs of the plants. Another common method of altering the exposure of the soil consists in the construction of beds, running through the whole length of the field, and separated from each other by furrows. The effect of this arrangement is to bring about a more rapid removal of water from surfaces of high water capacity, but, leaving out of account the fact that this result may be accomplished by simple means (water furrows), the process in question has the disadvantage of producing unequal heating of two oppositely inclined surfaces, resulting in unequal growth of the plants on the two sides. For this reason bed culture is not suited to fields that are to be planted with only one kind of crop. In such cases level cultivation, which secures a higher and more uniform temperature,[1] is decidedly preferable. If, however, this method is followed, the bed should run north and south if the field permits, since the difference in temperature between the east and west slopes is far less marked than that of slopes facing north and south. In other words, the disadvantage of unequal heating is least with beds running north and south.

---

[1] Forsch. Agr. Phys. [Wollny], 7 (1884), p. 52.

An excellent means of raising the temperature of the soil is the cultivation of plants in ridges or in hills. Soils so cultivated have a higher average temperature during the growing season than those cultivated level.[2] The effect is of longer duration in ridge culture than in hill culture, because in the former the ridges are constructed before seed time, while in the latter the hills are made only in the more advanced stages of growth of the plants. For this reason ridge culture is especially suited to plants which require a considerable amount of heat (maize, sunflower, beets, etc.) in climates unfavorable, as regards temperature, to the growth of these plants. However, this is true only for regions in which the weather in spring is not too cold, for the plants growing on the top of the ridges are, on account of their exposed position, more easily injured by late frosts in spring than those planted on the level soil and hilled up later. As a general rule, both these methods are mainly adapted to such soils as have little capacity for collecting and retaining heat (clayey and calcareous soils), and which are also apt to collect excessive quantities of water. It is evident that the increase of temperature due to ridge or hill culture is of no advantage on soils of little water capacity and great permeability (sand) when precipitation is scanty. Under such conditions level culture is to be preferred.[3] It should be remembered when ridge or hill culture is used that ridges running north and south are of higher and more uniform temperature than those running east and west.[4]

[2] Ibid., 3 (1880), p. 118.

[3] Ibid., 20 (1897–98), p. 493.

[4] Ibid., 8 (1885), p. 19.

Regulation of the store of water in the soil is another means of modifying the temperature. If the soil is wet, elevation of temperature is brought about by removal of the excess of moisture. The proper means to this end are direct removal of water, lowering water capacity, and increasing permeability of the soil, as already explained. That the desired result may be obtained by these means has been proved by various experiments.[1] Another means of changing conditions of temperature in soils is intermixture with soils of opposite properties as regards heat. Admixture of sand with clay or earth rich in clay and limestone results, under normal conditions, in an average increase in the temperature of the soil, while the opposite process produces a lowering of the temperature of the soil. By thoroughly intermixing sand and humus soil a soil results which collects heat more rapidly and to a greater depth than is done by either separately. Increase of humus in mineral soils, as, for instance, by the liberal application of manures of organic origin, prevents extremes of temperature.[2]

We thus see that not only the structure of the soil but also its temperature may be affected by mechanical means. Change from separate grain structure to crumbly structure[3] generally improves, though to a small degree, the heat conditions of a soil, principally by reducing evaporation.[4] Rolling the soil is more effective because it increases the conductivity of the soil for heat and therefore, under normal conditions of weather, raises the temperature of the soil.[5] Loosening the surface of the soil by harrowing, hoeing, etc., results, on the contrary, in a decrease in the temperature of the soil.[6]

By covering the ground with dead matter (mulching) the temperature of the soil is increased or decreased according to the behavior of the covering toward heat. If, for example, a thin layer of black material (coal dust, black clay slate, etc.) is spread over the soil, the temperature of the soil rises to a considerable degree[7] and crops on soils so treated are accordingly benefited.[8] Although this process, for evident reasons, is not applicable to cultivation on a large scale, still with delicate plants, especially in horticulture, it may be used to advantage. Spreading a layer of sand or gravel over humus soils causes a rise in the temperature of the latter, and wholly or partially prevents the frequent night frosts which occur during spring in such soils.[9]

Mulching with dead organic matter (stable manure, straw, etc.) may be used to lower the temperature of the soil during the warm portion

[9] Ibid., 17 (1894), p. 245.

of the year. By the same means the influence of the temperature of the air is diminished, and the soil protected from all excessive changes in temperature.[1] This is due to the fact that all the materials mentioned are poor conductors of heat. Allowing stable manure to remain spread out during the warm months on the surface of the soil for some time before it is worked into the soil may unfavorably affect the moisture of the soil. In the colder portion of the year, however, it may be beneficial on account of its influence in raising the temperature of the soil. Under such condition, however, the covering of manure may exercise a harmful influence on fine-grained clay soils rich in humus by preventing the loosening effect of frosts,[2] which is so important for such soils. Beneficial results may be obtained by thinly spreading a mulch in the late fall over fields occupied by perennial forage plants, thus protecting the plants against low, and especially changeable winter temperatures. As, however, such a covering retards warming of the soil, the undecomposed remains of the mulch should be removed as soon as the temperature begins to rise in the spring.

Keeping in mind the fact that covering the soil in this manner retards warming in spring, this practice may also be utilized to retard the blossoming of fruit trees, thus diminishing or preventing damage from late frost. If the ground surrounding the trunk is covered in spring with a heavy layer of straw, the temperature is kept low and in consequence the amount of water received through the roots is small, so that the development of the leaves, and especially the blossoms, is retarded for several weeks, or until the organs of reproduction are then in little danger of freezing.

Finally, the practice of keeping fields fallow (i. e., without crops) is a means of increasing the temperature of the soil during the warm season. When the rise in temperature is accompanied by an increase in the water content of the soil decomposition of organic materials is promoted,[3] and a greater or less quantity of plant food is stored in the soil. The only danger is that in permeable soils this plant food may be leached beyond the reach of the plants by heavy rains.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

A new method for the direct determination of alumina in the presence of iron, manganese, calcium, and magnesium, W. H. Hess and E. D. Campbell (*Jour. Amer. Chem. Soc., 21 (1899), No. 9, pp. 776-780*).—The authors found phenylhydrazine to be the most satisfactory of a long list of organic bases tried for the precipitation of the alumina. It precipitates the alumina from its solutions quantitatively, and, being a strong reducing agent, quickly reduces iron to the ferrous state, thus playing a double rôle. In carrying out the method the alumina solution, preferably in the form of chlorid, is heated to near the boiling point, dilute ammonia added slowly as long as the precipitate formed just redissolves with readiness, and a neutral saturated solution of ammonium bisulphite (made by passing sulphur dioxid into a cooled solution of ammonia, 1:1, until the solution becomes yellow) is added drop by drop to the hot solution until it becomes colorless, showing the complete reduction of the iron. To the hot solution 1 or 2 cc. of phenylhydrazine is added. If this does not suffice to produce a permanent precipitate, dilute ammonia may be added drop by drop until a permanent precipitate is just perceptible, and the precipitation then completed with a few drops more of the phenylhydrazine. The solution is filtered and the precipitate washed with warm water containing 5 to 10 cc. of phenylhydrazine bisulphite in 100 cc. of water, until the washings show no iron with ammonium sulphid. The bisulphite is made by adding a saturated aqueous solution of sulphur dioxid to phenylhydrazine until the crystals of phenylhydrazine sulphite which at first appear are redissolved to a yellow solution. This concentrated solution if well stoppered will keep indefinitely.

The precipitate with the filter is ignited in a platinum crucible and weighed. As the precipitate is very hygroscopic a second ignition and weighing is necessary. The phosphorus pentoxid determined in a separate sample is subtracted from the weight of the precipitate.

The iron may be determined in the filtrate from the alumina precipitate by precipitating with ammonium sulphid, redissolving the precipitate in dilute hydrochloric acid, and estimating in the usual way with ammonia after oxidation with nitric acid.

The phosphoric acid may be estimated by precipitating with phenylhydrazine, a sufficient amount of an excess of aluminum chlorid being added if the substance does not contain sufficient alumina to carry all the phosphoric acid as the normal phosphate. The precipitate may be dissolved in nitric acid and the phosphoric acid determined in the usual way, or it may be ignited and weighed, giving the combined weights of the alumina added and of the alumina and phosphoric acid in the substance. A number of determinations in known mixtures show very satisfactory results.

The estimation of arsenic in Paris green, T. SMITH (*Jour. Amer. Chem. Soc., 21 (1899), No. 9, pp. 769–772*).—The author proposes the following method: Two grams of Paris green is boiled for a few minutes with 100 cc. of water and 2 gm. of sodium hydroxid, allowed to cool to room temperature, made to 250 cc., filtered through a dry filter, and 50 cc. of the solution taken for analysis. The aliquot is concentrated to about half its volume, an equal volume of strong hydrochloric acid and 3 gm. of potassium iodid added, and the whole allowed to stand for 10 minutes. The deep-red solution is slightly diluted with water to dissolve the precipitate caused by the potassium iodid, and a dilute solution of sodium hyposulphite added until the color just disappears. The solution is then neutralized with dry sodium carbonate, and an excess of sodium bicarbonate added. The solution is then titrated with a decinormal iodin solution, or better, one in which 1 cc. of solution is equivalent to 0.005 gm. of arsenic trioxid. The number of cubic centimeters of such a solution multiplied by 1.25 gives the percentage of arsenic trioxid in the Paris green. With this method the author obtains duplicates differing within 0.05 per cent, and the results check very closely with the gravimetric methods. Less than an hour is required for an analysis.

Determination of dextrose in the presence of cane sugar, JESSEN-HANSEN (*Medd. Carlsberg Lab., 4 (1899), p. 314; abs. in Chem. Ztg., 23 (1899), No. 74, Repert., p. 273*).—The author has made many experiments in the line of those of Kjeldahl, and prepared tables for the calculation of dextrose in mixtures of dextrose and cane sugar. He finds that with slight modifications of the conditions described by Kjeldahl useful results may be obtained. If twice the amount of potassium-sodium tartrate prescribed by Kjeldahl is employed and the time of heating shortened to 5 minutes, only about 14 mg. of copper will be thrown down by 10 gm. of cane sugar (instead of 110 mg. as under the former conditions), and if the time is measured exactly concordant results will be obtained.

Studies on malic acid, HILGER and H. LEY (*Chem. Ztg., 23 (1899), No. 80, p. 584*).—The chemical characteristics of malic acid prepared from the fruit, berries, and other parts of various plants was studied, and also the method of quantitative determination. Palladious chlorid was found to be a means for the determination of malic acid in the presence of tartaric acid, etc., especially in wine. With the exception of glycerin no normal constituent reduces alkaline palladious chlorid, while malic acid separates out the metallic palladium after 10 minutes' boiling. This can be collected in an Allihn's tube and weighed direct. In determining malic acid in wine the wine is evaporated to about one-third, the acids precipitated with lead acetate, and the precipitate redissolved by hydrogen sulphid or carbonic acid.

A contribution to the chemistry of butter fat. II, Chemical composition of butter fat, C. A. BROWNE, Jr. (*Jour. Amer. Chem. Soc., 21 (1899), No. 10, pp. 807–827*).—Continuing his previous investigations (E. S. R., 11, p. 308), the author has analyzed the soluble and insoluble fatty acids, and studied the glycerids of butter fat. He gives the methods and results, together with notes on the accuracy of the methods employed.

Composition of butter fat.

	Acids.	Triglycerids.
	Per cent.	*Per cent.*
Insoluble acids:		
Dioxystearic	1.00	1.04
Oleic	32.50	33.95
Stearic	1.83	1.91
Palmitic	38.61	40.51
Myristic	9.89	10.44
Lauric	2.57	2.73
Soluble acids:		
Capric	.32	.34
Caprylic	.49	.53
Caproic	2.09	2.32
Butyric	5.45	6.23
Total	94.75	100.00

"Other bodies, such as coloring matter, lecithin, cholesterin, phytosterin, etc., which occur in butter fat in only minute quantities, have not been considered in the above analysis. These substances go to make up the unsaponifiable matter of butter fat, the total amount of which we have found to be only about 0.1 per cent.

"We have made an elementary analysis of butter fat and find the agreement between the actual percentages of carbon, hydrogen, and oxygen, and the theoretical figures, as calculated from the percentages of the various glycerids in the preceding table, to be very close.

Elementary composition of butter fat.

	Carbon.	Hydrogen.	Oxygen.
	Per cent.	*Per cent.*	*Per cent.*
Actual	75.17	11.72	13.11
Theoretical	74.86	11.71	13.43

"The close agreement between these two sets of results would indicate that the figures expressing the percentages of acids and glycerids are not very far removed from the truth. . . .

"While the evidence is strongly in favor of the existence of complex glycerids, there are equally good reasons for believing in the existence of simpler bodies. An analysis of the fatty acids from the different fractions of the butter oil and butter palmitin would throw much light upon the constitution of the glycerids contained therein. For such work, however, our time has been too limited. We hope, if possible, in the future to continue our work in this direction."

A contribution to the chemistry of butter fat. III, The chemistry of rancidity in butter fat, C. A. BROWNE, Jr. (*Jour. Amer. Chem. Soc., 21 (1899), No. 11, pp. 975–994*).—The term rancidity is used to mean not merely a development of free acid, but any chemical or physical change in the character of a fat from the normal. The author points out the distinction between rancid butter and rancid butter fat. The present investigations were confined entirely to pure butter fat and not to butter.

The changes undergone by a sample of butter fat during 8 months are given, showing that with the development of rancidity there was a decided increase in the acid, saponification, and Reichert numbers, a slight increase in the ether number, and a very marked decrease in the iodin absorption. Additional data for 4 samples of fresh and rancid butter fat show that with the advance of rancidity there is an increase in the acetyl number and a decrease in the percentages of insoluble acids and glycerol.

The effects of rancidity upon the acids of butter fat are discussed at considerable length. Elementary analyses of fresh butter fat and rancid butter fat 2 years old showed "that the effect of rancidity is to cause a decrease in the percentages of carbon and hydrogen, with a corresponding increase in the percentage of oxygen."

The increase of the saponification number as rancidity advances is explained by the breaking up of higher acids into acids of lower molecular weight, which is confirmed by the decrease in percentage of insoluble acids and the increase in the Reichert number. Little difference was found in the majority of experiments between the molecular weights of the volatile acids from fresh and rancid samples, the general tendency seeming to be toward a slight decrease in this constant as the butter fat became rancid.

"In the development of acidity there seems to be a gradual breaking up of all the glycerids," although the first change is apparently an oxidation of some of the oleic acid. The author notes that the amount of free volatile or soluble acids in rancid butter fat is much smaller than might be expected, and states in explanation of this that "the first products formed by the decomposition of oleic acid are not of an acid but of an aldehyde nature. These aldehyde bodies are further changed by oxidation into soluble acids, but this takes place only in a very advanced stage of rancidity." In the process of saponification with alcoholic potash these aldehydes are decomposed into acids. This also is given as an explanation of another fact, namely, the increase in the ether number with rancidity, while theoretically the quantity of neutral fat (represented by ether number) should become steadily less. The presence of aldehydes vitiates the true ether number. The following table is given as showing the probable manner in which the oleic acid of butter fat is decomposed:

Decomposition of oleic acid in butter fat.

Butter fat.	Condition.	Oleic acid.	Insoluble acids.	Loss in oleic acid.	Loss in insoluble acids.	Acetyl number.	Increase in acetyl number.	Increase in oxy-acids.
		Per cent.	*Per cent.*	*Per cent.*	*Per cent.*			*Per cent.*
No. 1	Fresh	38.28	88.96	....	....	3.5	....	....
No. 1	Rancid	31.85	85.06	6.43	3.90	10.9	7.4	1.78
No. 2	Fresh	32.81	86.41	....	....	4.1	....	....
No. 2	Rancid	21.93	80.42	10.88	5.99	15.1	11.0	2.51
No. 3	Fresh	38.76	88.46	....	....	3.8	....	....
No. 3	Rancid	25.03	81.15	13.73	7.31	18.0	14.2	3.28
No. 4	Fresh	38.79	87.72	....	....	....	....	....
No. 4	Rancid	9.49	72.03	29.30	15.69	....	....	....

"The loss in insoluble acids accounts for but little more than half the loss in oleic acid; the ratio seems to be a fairly constant one, and averages about 55 per cent. This figure, then, may be taken to represent approximately the amount of oleic acid in the loss which is converted into lower soluble acids. Calculating the increase in the acetyl numbers to dioxystearic acid will make up about 25 per cent more of this loss in oleic acid, thus leaving about 20 per cent still unaccounted for; the formation of insoluble aldehyde products during the saponification may explain this discrepancy."

The reason for the decrease in the percentage of glycerol as rancidity advances is discussed without arriving at any satisfactory explanation. The effects of rancidity upon the physical constants of butter fat are shown, there being an increase in the specific gravity, something of a decrease in the temperature at which turbidity appears (critical temperature), and an increase in the refractive index. The combustions in a bomb calorimeter showed a marked decrease in the heats of combustion of rancid fat.

Report of chemist, R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 19–29*).—A summary account of the work of the chemist during the year, including especially analyses of fertilizers, oat grains and hulls (food constituents), and roots and tops of common red, mammoth, and alsike clover, and alfalfa at different stages of growth (fertilizing constituents), and a study, including digestion experiments, of the effect of the stage of growth on the composition of alfalfa (see p. 662).

Chemistry: Its evolution and achievements, F. G. WIFCHMANN (*New York: William R. Jenkins, 1899, pp. 176*).—The author discusses the growth of chemistry from the early alchemists to the present time. The great discoveries and the more important theories are spoken of, and much historical matter gathered from a variety of sources is brought together in concise form. A somewhat detailed name and subject index adds to the usefulness of the volume.

Plant and agricultural chemistry, M. BERTHELOT (*Chimie végétale et agricole. Paris: Masson & Co., 1899, vols. 1, pp. XVI+511, figs. 4; 2, pp. VI+441, figs. 3; 3, pp. VI+517, figs. 6; 4, pp. VI+528, figs. 2*).—This book is a collection of the reports of the work of the author, especially at the station for plant chemistry at Meudon, which have appeared from time to time in the *Annales de Physique et Chimie*. The first volume deals with the fixation of free nitrogen by soils and by plants, the second volume is devoted to general studies on plant growth and the chemical action of light, the third includes special studies on plant growth, and the fourth is devoted to studies of cultivated soils and of wine and its bouquet. Of the many valuable papers included in these volumes those relating to the author's noted investigations on the fixation of the free nitrogen of the air by soils and plants are especially interesting and important.

Dairy chemistry: A practical handbook for dairy chemists and others having control of dairies, H. D. RICHMOND (*London: Chas. Griffin & Co. Ltd., 1899, pp. 384, figs. 22*).—This is a comprehensive treatise on the chemistry of milk and dairy products and the methods of analyzing them and of conducting dairy inspection. The 8 chapters treat of the constituents of milk, the analysis of milk, adulterations and alterations of normal milk and their detection, chemical control of the dairy, biological and sanitary matters, butter, other milk products, and the milk of mammals other than the cow. A large number of useful tables are incorporated in the body of the book and in an appendix, and a chapter is added on the standardization and calibration of apparatus. The author is the analyst to the Aylesbury Dairy Company and is well known as a dairy chemist. The large amount of analytical data and observations accumulated by his predecessor, Dr. Vieth, during the period of 12 years in which he occupied the position of analyst in the above company, has been made use of in preparing the book.

Dictionary of industrial chemistry in its relation to manufacturing, metallurgy, agriculture, pharmacy, pyrotechnics, arts, and manufactures, A. M. VILLON and P. GUICHARD (*Dictionnaire de chimie industrielle, contenant les applications de la chimie a l'industrie, a la métallurgie, a l'agriculture, a la pharmacie, a la pyrotechnie et aux arts et métiers. Paris: Tignol, 1899, vol. 2, pp. 104, ill.*).

Practical manual of the analysis of alcohols and spirits, C. GIRARD and L. CUNIASSE (*Manuel pratique de l'analyse des alcohols et des spiritueux. Paris: Masson & Co., 1899, pp. VIII+445*).

A quarterly review of the progress in medical chemistry, T. PANZER (*Oesterr. Chem. Ztg., 2 (1899), No. 15, pp. 363, 364*).—The greater part of this article is devoted to a review of the recent work on albuminoids.

Guide to the chemical analysis of alimentary substances, A. GADOLA (*Guida per le recerche chimiche sulle sostanze alimentari. Caserta: S. Marino, 1899*).

Chemistry of essential oils and artificial perfumes, E. J. PARRY (*London: Scott, Greenwood & Co., 1899, pp. 411, figs. 20*).

On the volumetric determination of zinc, POUGET (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 1, pp. 45-47*).

Basis for the examination of butter by the refractometer, A. PARTHEIL (*Chem. Ztg., 23 (1899), No. 80, p. 584*).—Pure preparations of the principal constituents of butter fat were tested in the refractometer. The values obtained indicate that the parallelism observed in practice between the iodin number and the index of refraction rests upon a scientific basis, but that no parallelism was apparent between the Reichert Meissl number and the index of refraction or the temperature coefficient for the reaction.

Cryoscopy of butter and margarin, POURET (*Bul. Soc. Chim. Paris, 3. ser., 22 (1899), No. 15, pp 738-740*).

Determination of acidity of must, wines, and vinegars by eudiometric method, A. BERNARD (*Bul. Soc. Nat. Agr. France, 59 (1899), No. 7, pp 505-510*).

The examination of malt, L. AUBRY (*Chem. Ztg., 23 (1899), No. 80, pp. 849, 850*).—A description of methods.

The accuracy of the Jorgensen method of estimating boric acid in preserved meat and the separation of the boric acid and borax, A. BEYTHIEN and H. HEMPEL (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 11, pp. 842-851*).

A chemical study of wheat, C. B. FRANKFORTER and E. P. HARDING (*Jour. Amer. Chem. Soc., 21 (1899), No. 9, pp. 758-769*).—This investigation relates to wheat oil—its viscosity, index of refraction, absorption spectrum, saponification number, iodin number, and acid number, and the determination of glycerol, lecithin, and parocholesterol.

The chemical changes in rye and wheat during molding and sprouting, R. Scherpe (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 7, pp. 550–558*).– The investigation covers changes in weight of the dry matter, nitrogen, starch, water-soluble carbohydrates (those soluble by the aid of diastase), pentosans, cell material, fat, and ether extract. In addition the acidity, ammonia, water soluble substance, together with its nitrogen and ash content, water-soluble carbohydrates, the nitrogen of pure protein, and the fat and ether extract were studied more especially from a chemical standpoint.

Chemical examination of tobacco smoke, H. Thoms (*Chem. Ztg., 23 (1899), No. 80, pp. 852–854*).—A paper presented at the Munich meeting of the Association of German Naturalists and Physicians. The points investigated were (1) the nicotin and ash content of the cigars used, (2) what bases pass into the smoke? (3) what acids are formed during smoking? (4) what is the nicotin content of the cigar stub remaining after smoking? and (5) does tobacco smoke contain carbonic oxid or other poisonous body?

On the occurrence of barium in plants and in soils, R. Hornberger (*Landw. Vers. Stat., 51 (1899), No. 6, pp. 473–478*).—The ash of the trunk wood of 2 copper beeches, 102 and 105 years old, was found to contain from 0.97 to 1.2 and 0.57 to 0.9 per cent of barium oxid (BaO), respectively. Four hundred grams of the soil on which these trees grew, extracted with hot 5 per cent hydrochloric acid, yielded 9 mg. of barium sulphate. Similar observations by other investigators are noted.

The occurrence of chlorin-containing organic compounds in cotton-seed oil, and the nonexistence of sulphur-containing bodies in the same, P. N. Raikow (*Chem. Ztg., 23 (1899), Nos. 75, pp. 769, 770; 77, p. 802*).

Further investigations on the volatile mustard oil prepared from a number of samples of rape-seed cake, G. Jörgensen (*Landw. Vers. Stat., 52 (1899), No. 4, pp. 269–290*).

Hazel-nut oil, J. Hanuš (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 8, pp. 617–622*).—The author reports a study of the composition of this oil

Formation of furfurol from starch and its derivatives, F Sestini (*L'Orosi, 20 (1898), p. 325; abs. in Analyst, 24 (1899), No. 279, p. 157*).

On the constitution of vegetable alkaloids, X. Causse (*Ann. Univ. Lyon, n. ser., 1 (1899), No. 2, pp. 99*).

Carbon bisulphid (*L'Engrais, 14 (1899), No. 42, pp. 1000–1002*) —A discussion of its properties, manufacture, uses, and application in agriculture and viticulture.

Some boiling point curves, II, J. H. Haywood (*Jour. Amer. Chem. Soc., 21 (1899), No. 11, pp. 994–1001*).—The author has worked out the curves for mixtures of benzene or methyl alcohol with chloroform, carbon tetrachlorid, ether, and acetone.

Rise and development of the liquefaction of gases, W. L. Hardin (*New York: Macmillan Co., 1899, pp. 250, figs. 42*).

Indicators and test papers—their source, preparation, application, and tests for sensitiveness, A. I. Cohn (*New York: John Wiley & Sons; London. Chapman & Hall, Ltd., 1899, pp. IX+249*). –The title page states that this is "a résumé of the current facts regarding the action and application of the indicators and test papers which have been proposed from time to time, and are in present use in chemical manipulations, with a tabular summary of the application of indicators, designed for the use of chemists, pharmacists, and students."

Apparatus for preventing the backward flow of water during exhaustion with a water-pump, G. Chatanay (*Jour. Pharm. et Chim., 6. ser., 9 (1899), No. 11, pp. 524–527, fig. 1; abs. in Jour. Chem. Soc. [London], 76 (1899), No. 444, II, p. 646*).

The physical-chemical laboratory of the University of Giessen, K. Elbs (*Chem. Ztg., 23 (1899), No. 76, pp. 766–768, figs. 4*).—A description with plans.

State analytical laboratories, J. Graftiau (*Ann. Sci. Agron., 1899, II, No. 1, pp. 122–129*).

METEOROLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review, 27 (1899), Nos. 7, pp. 287–341, pls. 3, figs. 6, charts 8; 8, pp. 343–393, pls. 2, figs. 2, charts 12; 9, pp. 395–448, fig. 1, charts 11*).—In addition to the usual reports on forecasts and warnings and on weather and crop conditions, and meteorological tables and charts, No. 7 contains special contributions on Cold waves in the Southwest, by J. S. Hazen; Every man his own weather prophet, by J. H. Hopkins; A study of temperatures at Baltimore, Md., by F. J. Walz; Special report on the flood in the Brazos River Valley, Texas, June 27 to July 15, 1899, with notes of previous overflows of the Brazos (illus.), by I. M. Cline; Volcanic eruptions in Hawaii, by C. J. Lyons; The tornado at New Richmond, Wis. (illus.), by O. G. Libby; The use of the storage battery for the electrical recording instruments, by E. C. Vose; Irrigation by wire, by A. Betts; Climatology of the Isthmus of Panama, by H. L. Abbott; Tornado observations, by A. H. Gale; The force of a tornado, by B. F. Groat; Sudden oscillations in lake level—pressure waves (illus.), by A. J. Henry; and Tornado, hurricane, and cyclone, by H. M. Watts; and notes by the editor on effect of wind, on catch of rainfall, seismograph stations in the United States, temperatures in the sunshine, destructive frost of June 30, 1899, in Ohio, chalk-plate maps, tornado phenomena, local winds that are not tornadoes, spurious tornado photographs, general forecasts for Washington, Oregon, and Idaho, the present status of meteorology, the diurnal variation of the barometer, and river discharges in Colorado.

No. 8 contains special contributions on Waterspouts at Key West, Fla. (illus.), by H. R. Boynton; Water temperatures of the Great Lakes, by N. B. Conger; Conduct and the weather,[1] by E. G. Dexter; Automatic records of a thunderstorm (illus.), by H. H. Kimball; Thunderstorms on August 2, 1899 (illus.), by A. J. Henry; and notes by the editor on a newspaper tornado fake, display of forecast cards on street letter boxes, improvements in map of the section reports, chemistry of vegetation, the direction of rotation, standard time, the ether and the atmosphere, from Honolulu to Iowa, do local storms follow river valleys? Weather Bureau men as university lecturers, the weather and the dairy, ball lightning, fillet or ribbon lightning, distant lightning, the storms of August 2, air currents in thunderstorms, ancient tornado tracks, the second Wellman expedition, and a successor to Senor Barcena (Manuel E. Pastrana).

No. 9 contains special contributions on The origin, paths, and limiting zones of the typhoons of the Orient, by P. Bergholz (translated by C. Abbe); The international cloud work of the Weather Bureau, by F. H. Bigelow; Floods and flood problems, by H. C. Frankenfeld; Small whirling columns of mist, by R. B. Marean; Additional observations of the St. Kitts, W. I., hurricane, by W. H. Alexander; and Proceedings of the meeting of the International Meteorological Committee, at St. Petersburg, September 2-7, 1899, by A. Lancaster; and notes by the editor on results of work with balloons and kites at Trappes, France (illus.), preliminary results of Weather Bureau kite observa tions in 1898, the average temperature of the atmosphere, the International Electrical Congress at Como, Italy, instructive laboratory experiments (on the dynamics of the air), meteorology in our universities, Weather Bureau men as university lecturers, minimum temperatures on mountain peaks, August weather on the Pacific Coast, the calculation of the resultant wind, and probable cloudiness during total solar eclipse of May 28, 1900 (see below).

---

[1] Abs. from Psych. Rev., Monograph Sup. No. 10, pp. 104.

Report of the Chief of the Weather Bureau for 1899, W. L. MOORE (*U. S. Dept. Agr., Weather Bureau Doc. 206, pp. 23*).—This is a report of the operations of the Weather Bureau during the fiscal year ended June 30, 1899. In addition to a general summary of the work of the year, this report discusses briefly the West Indian service; the convention of Weather Bureau officials at Omaha, Nebr., October 13-14, 1898; loss of life and property in the United States by lightning in 1898; meteorological charts of the Great Lakes; aerial observations; international cloud observations; plateau barometry; climate and crop work; Monthly Weather Review; California rainfall and Alaskan temperatures; distribution of forecasts and warnings, and a number of other less important topics.

Meteorology, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 2, 3*).—Tridaily observations on dew point and humidity during 5 months (June-October) of 1898 are reported and briefly discussed.

About the weather, M. W. HARRINGTON (*New York: D. Appleton & Co., 1899, pp. XX+246, pl. 1, figs. 48*).—This is the first of a series of "Home Reading Books" edited by W. T. Harris, U. S. Commissioner of Education. The subjects discussed are: The contest of mankind with the weather; remedies against injuries by weather; pressure of the air and its measurement; kinds, distribution, velocity, and measurement of winds; temperature; humidity or moisture—dew, fog, cloud, rain, and snow; cyclones or lows and anticyclones or highs and the weather accompanying them; tornadoes; ice, sleet, ball snow, and hail; thunderstorms and cloud-bursts, lightning and thunder; diurnal and annual changes in weather; local influences on weather; weather predictions; progress of knowledge of the weather; simple experiments with air; familiar effects of weather changes.

In a brief introductory chapter the editor explains the plan and purpose of this series of books.

Vertical gradients of temperature, humidity, and wind direction, H. C. FRANKENFELD and C. F. MARVIN (*U. S. Dept. Agr., Weather Bureau Bul. F (Doc. 208), pp. 71, pls. 4, figs. 6*).—This is a preliminary report on kite observations at 17 stations in the United States during the year 1898, with an introductory chapter on the construction and operation of the kite meteorograph. "The temperature conditions at all elevations and under varying conditions of weather and time have been computed in terms of the gradient in degrees Fahrenheit for each 1,000 ft., and in the increase of elevation necessary to cause a fall of 1 degree in the temperature. The mean results, however, are given only in degrees per thousand feet."

The probable state of the sky along the path of total eclipse of the sun, May 28, 1900, observations of 1899, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bureau Bul. 27, pp. 23, charts 4*).—This is the third report (E. S. R., 10, p. 827) on observations to determine the prevailing average cloudiness in the districts covered by the eclipse track.

The mild temperature of the Pacific Northwest and the influence of the "Kuro Siwo," B. S. PAGUE (*Portland, Oreg.: Weather Bureau Print, 1899, pp. 11, charts 3*).—This paper, which is published by permission of the Chief of the U. S. Weather Bureau, undertakes to demonstrate that the mildness of the temperature of the Pacific Northwest is not due to the influence of the Kuro Siwo, or Japan current, but is a result of the dynamic heating due to compression of the air descending the Pacific slope.

Variations in lake levels and atmospheric precipitation, A. J. HENRY (*U. S. Dept. Agr., Weather Bureau Doc. 203, pp. 8, dgms. 3*).—This article summarizes the records of past years with a view to showing whether there is any definite relation between precipitation and the average level of the Great Lakes.

It is stated that "it seems possible to indicate the level of the Lakes, approximately at least, by closely observing the precipitation in the various watersheds, especially the amount of snow and the manner of its disappearance. All inferences as to the probable effect of precipitation on Lake levels must be contingent, however, upon the maintenance of a constant cross section and slope in the present connecting channels."

An advance in measuring and photographing sounds, B. F. SHARPE (*U. S. Dept. Agr., Weather Bureau Doc. 202, pp. 18, pls. 7, figs. 3*).—An article reprinted from the *Monthly Weather Review, 27 (1899), No. 5, p. 205.*

The carbon dioxid of the ocean and its relations to the carbon dioxid of the atmosphere, C. F. TOLMAN (*Jour. Geol., 7 (1899), No. 6, pp. 585–618, figs. 6*).

WATER—SOILS.

Cooperative experiments in soil moisture, J. B. REYNOLDS (*Ontario Agr. and Expt. Union Rpt. 1898, pp. 57–60*).—A brief account is given of observations during one month on clay loam soil planted in turnips, light sandy loam in barley, and heavy clay in winter wheat.

The following method of taking samples of soil was used and proved very satisfactory:

"The apparatus consists of a brass tube 1 ft. long, with an inside thread cut at one end. Into this end fits an iron shank, about 3 ft. long, having a similar outside thread cut at one end and with a large eye at the other, into which a wooden handle fits. The other extremity of the brass tube is fitted with short curved steel knives, which serve the purpose of cutting out a tube of soil. [See also p. 625.] The sample is taken by a combination of boring and downward pressure and the tube of soil passes up the brass tube until the latter is filled. Then the filled tube is unscrewed from the shank, slipped into a tin case previously labeled, and the tin case is then corked tightly and put into a wooden box. The end of the box slides in and out of a snugly fitting groove, and when the box is thus closed there is little chance for the moisture to escape from the soil within.

"After the first tube has been removed from the shank a second is screwed on and a second boring is made just below the former, and after that a third. It has been our practice so far to take 3 depths—2 a week; and as the wooden box will contain just 6 tubes each box represents 1 week's work. When filled the box is shipped to the laboratory for the determination of the moisture content."

The sediment content of irrigation water J. D. KOBUS (*Meded. Proefstat. Oost Java, 3. ser., No. 14, pp. 24*).—Observations on the sediment content of a large number of samples of water taken at different dates from 6 sources of supply for irrigation purposes are reported. The average amount of sediment in the 6 cases varied from

131 to 422 mg. per liter. The phosphoric acid in the sediment varied from 0.3 to 1.7 per cent; potash from 0.21 to 0.6 per cent; the nitrogen from 0.16 to 0.4 per cent.

Contributions to the study of Russian soils, A. SOVIETOV and N. ADAMOV (*St. Petersburg, 1899, pt. 12, p. 137; rev. in Selsk. Kohz. i Lyesov., 193 (1899), June, pp. 718, 719*).—Of the articles in this publication two are of especial interest. The first, The phenomena of reaction between the mineral and organic parts of the soil, by P. Lyashchenko, gives the results of investigation on the chemical properties of humus These investigations corroborate the view advanced earlier by some scientists that humus is capable of decomposing mineral salts, both soluble and insoluble, and also natural minerals. The author finds that the admixture of salts with the humic substances increases this decomposition. Thus the reaction between the mineral and organic parts of the soils may be considered as a simple chemical reaction, which, among other things, fully explains the vegetable origin of chernozem.

The second article, The development of the root system in plants in dependence on the concentration of the soil solutions, by S. Kravkov, reports experiments which lead to the conclusion that there is a regular correlation between the concentration of the aqueous solution of the soil and the life of the roots (of barley). The author concludes that the roots of plants usually depend for their nourishment entirely upon the materials in solution in the soil, and only make use of their ability to take up plant food from the solid particles of the soil by means of acid secretions under unusual conditions or at critical periods of the life of the plant.—P. FIREMAN.

Some methods for the determination of the productiveness of soils, W. W. WINNER (*Izv. Moscow Selsk. Khoz.-Inst., 5 (1899), No. 2, pp. 117-144*).—The author explains his method of making a soil survey of an extended area. For this purpose a large number of samples of soil are taken and observations on topography and surface geology of the locality and the physical characteristics of the different soil layers are made, the level of the ground water, etc., being at the same time recorded. The samples so collected are classified as regards their more important features. The separate groups are then subjected to a preliminary examination with a view to more accurate classification and the selection of the samples requiring detailed examination. In this preliminary examination determinations are made of (1) the undecomposed mineral matter ("skeleton") of the soil, (2) the products of weathering (clay and zeolites), and (3) the humus content. The first throws light on the origin of the soil, the second and third on its formation and present condition.

The separation of the clay and zeolites from the undecomposed "skeleton" presents great difficulties. For the estimation of the former the author prefers a method based on the determination of chemically combined water. Chemically combined water is a necessary constituent not only of clay, but of all its components, namely, of zeolites and hydrated combinations of oxid of iron, alumina, and silicic acid; and in these substances the water content fluctuates within narrow limits (10 to 20 per cent), approaching that of kaolin, which, according to the formula Al_2O_3, $2SiO_2$, $2H_2O$, is about 14 per cent.

The chemically combined water is determined by subtracting from the total loss on ignition the weights of the humus and of the hygroscopic water. From the amounts of chemically combined water thus determined the proportions of zeolites and clay in the soil are estimated.

This method was compared with the mechanical method on 6 different soils. The average content of clay by the mechanical method was 11.4 per cent, by the author's method 11.2 per cent. The agreement was close, except in case of sandy and very clayey soils. The author's investigations indicate that with such soils the mechanical method gave too low results. On the whole, the combined-water method gave very satisfactory results on clayey, medium, and sandy soils.

The determination of humus presents little difficulty, and skeleton may be determined by difference. It is sometimes desirable in addition to the above to determine carbonates and soluble salts (alkali), but this is easily done.

By means of the preliminary examination the number of samples requiring detailed examination is greatly reduced. In the latter the same objects are kept in view as in the preliminary study, viz, the origin, processes of formation, and present condition of productiveness.

Conclusions as to the first two points are based upon the field and geological observations and upon (1) changes in the mechanical composition of the skeleton, as determined by comparing the mechanical composition of the subsoil, soil, and the intermediate horizon; (2) the degree of the weathering of the soil, as compared with parent rock, as determined by the data as to the chemically combined water; (3) the changes in the composition of the products of the weathering, as determined by the amount and composition of the zeolitic portion of the soil and subsoil; (4) the changes in the contents of carbon dioxid in different horizons, and (5) the distribution of organic matter in the various horizons. To ascertain these and many other features recourse must be had to the most varied methods.

For testing the productiveness of the different soils the author uses the so-called "culture method." This consists of testing the soils in pots under different crops with and without fertilizers. In experiments with 6 different soils on which oats, vetches, and millet were grown the crops showed an increase of yield, due to fertilizers inversely proportional to the richness of the soil, the richness of the soil being measured by the amount of humus and clay present. The author holds that the productiveness of soils is a resultant of two mutually opposing factors, richness and activity of soils, the activity of soils being measured by the proportion of sand particles larger than 0.01 mm.

In laboratory experiments undertaken with the object of determining the energy of the decomposition of humus and the formation of nitrates it was found that the formation of carbon dioxid was inversely proportional to the humus content of the soil, and that the smaller the nitrogen content of the soil the more energetic (relatively) the formation of nitrates.—P. FIREMAN.

Determination of soil moisture, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 3, 4*).—The methods of taking samples and determining moisture are briefly described. "The sampler used consists of a seamless brass tube 1 ft. in length and ⅞ in. in diameter, with a female thread at one end. To fit this, an iron shank about 3 ft. long, with a similar thread outside was made. Through the top of the shank a wooden handle 2 ft. long passed to serve as a lever in turning the instrument and boring into the soil. Into the other extremity of the brass tube were fixed 2 closely fitting knives, about ½ in. long, made of the hardest steel, and slightly curved so as to cut out a tube of soil somewhat smaller than the brass tube through which the soil passes."

Analyses of rose soils, W. FREAR and C. P. BEISTLE (*Amer. Gard., 20 (1899), Nos. 261, p. 872; 262, p. 894*).—Mechanical and chemical analyses (including solubility in 1 per cent citric acid) of 3 samples of soil used for culture of roses are reported, and their adaptability to the purpose for which they are used is briefly discussed.

The effect of surface cultivation on the moisture of the soil, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 4, 5*).—This is an account of observations during May, June, and July on the moisture content (at depths of 1, 2, and 3 ft.) of plats, 1 rod square, on some of which the soil was kept loose and on the rest compact. The conclusions reached are that "(1) surface cultivation conserves moisture, and the drier the weather the greater is the relative effect; and (2) surface cultivation keeps the ground in better condition for lifting the water from below to the roots of plants."

FERTILIZERS.

On the relative value of street sweepings and farmyard manure, S. RHODIN (*K. Landt. Akad. Handl., 38 (1899), No. 2, pp. 82–99*).—The author gives a general discussion of the character and value of street sweepings and their application for fertilizing purposes in different countries in the Old and New World. In order to determine what proportion of street sweepings from Stockholm, Sweden, was of actual manurial value and what was useless admixtures, a carload lot of the sweepings weighing 7,900 kg. was picked over. Ninety-one per cent of the sweepings was found to consist of materials like horse manure, wood ashes, animal and vegetable refuse matter, which are of direct fertilizing value. The rest, 9 per cent, was made up of useless admixtures like paper and pasteboard (2.5 per cent), rags (1.3 per cent), raw bones (0.9 per cent), straw and bast (0.8 per cent), glass (0.9 per cent), stoneware and chinaware (0.4 per cent), stone and slag (0.9 per cent), tin plate and tin cans (0.4 per cent), etc.

For the purpose of determining the actual fertilizer value of street sweepings as compared with different kinds of farmyard manure, experiments were made with peat manure, straw manure, and street sweepings on the experimental farm at Albano, Sweden. The peat manure was from the Stockholm street-car stables, in which peat is used as an absorbent. The straw manure was from cow stables mainly. The composition of these materials was determined by chemical analysis, as follows:

Composition of peat manure, straw manure, and street sweepings.

	Peat manure (per cub. meter of 550 kgs.).	Straw manure (per cub. meter of 687 kgs.).	Street sweepings (per cub. meter of 471 kgs.).
Soluble in 2 per cent hydrochloric acid:	*Kgs.*	*Kgs.*	*Kgs.*
Potash	3.55	2.90	2.00
Lime	1.26	2.90	22.00
Phosphoric acid	1.70	3.50	.95
Ammonical nitrogen	1.00	.64	.08
Organic nitrogen	2.00	4.50	3.30
Organic matter	86.60	127.00	93.00

The value of a cubic meter of the three materials, according to Swedish valuations of fertilizing materials, was $1.24, $1.83, and $1.17, respectively.

In studying the comparative fertilizing value of the fertilizers mentioned, a piece of land 1.8 acres in extent was divided into 9 equal plats, 3 of which received no manure, 3 straw manure, and 3 sweepings. Barley was grown on the plats in 1897 and oats in 1898. No manure was applied in 1898. On another field of 2.47 acres a similar division was made and the same fertilizers applied, with peat manure in addition. Beans were grown on this plat. The soil in case of both fields was a heavy clay. Seventeen loads of manure per acre were put on the barley field and 65½ loads on the bean field. The average results obtained are shown in the following summary table:

Yields per acre of barley, oats, and beans with different kinds of manure.

	Barley, 1897.			Oats, 1898.			Beans, 1898.		
	Grain.	Straw.	Net return.	Grain.	Straw.	Net return.	Beans.	Vines.	Net return.
	Lbs.	*Lbs.*		*Lbs.*	*Lbs.*		*Lbs.*	*Lbs.*	
Straw manure	2,661	3,567	$44.75	2,270	4,124	$51.72	4,434	5,155	$70.69
Peat manure	....	....	....	....	....	....	4,866	5,667	89.74
Sweepings	2,360	3,253	33.78	2,153	3,845	46.00	4,302	4,560	62.40
Unmanured	1,843	2,658	28.93	1,763	3,276	37.29	....	....	....

The figures given for net returns were obtained by deducting the cost of growing the crops and the cost of manure from the value of the product. It will be seen that even if street sweepings do not possess the high value of either peat manure or straw manure they are profitable fertilizing materials.

Favorable practical experience as to the application of sweepings as a farm manure on land of different character is cited.—F. W. WOLL.

On the effect of animal manures on marsh soils, P. HELLSTRÖM (*K. Landt. Akad. Handl., 33 (1899), No. 3, pp. 167–171*).—As a contribution to the question of the effect and relative value of manure from different farm animals on marshy soils, the author conducted pot experiments in zinc cylinders 30 cm. high and 25 cm. in diameter. The fertilizers applied were extracts of horse, sheep, and cow manure, liquid manure, and slaked lime. The manure extracts were either applied directly or after having been previously sterilized by boiling on 3 successive days for 30, 10, and 10 minutes, respectively. Each pot received the equivalent of 2.5 gm. of manure. Two pots were left unmanured. The pots were filled with soil from a new-broken marsh which had not been fertilized and had not grown any crop. Peas were planted in the boxes, and after germination were thinned to the same number of plants in each pot. The average results for the different fertilizations are shown in the following table:

Data for 10 pea plants grown with different fertilizers on marshy soil.

	Peas.	Vines.	Peas and vines.	Number of pods per 10 plants.	Average weight of peas.
	Grams.	*Grams.*	*Grams.*		*Gram.*
No manure	5.51	10.92	16.43	14	0.134
Lime	7.29	16.39	23.68	20	.162
Sheep manure extract	9.12	16.71	25.83	21	.160
Sheep manure extract, sterilized	6.84	13.26	20.10	14	.156
Horse manure extract	7.55	17.15	24.70	23	.161
Horse manure extract, sterilized	6.52	13.49	20.01	17	.138
Liquid manure	12.40	17.25	29.65	17	.165
Liquid manure, sterilized	9.88	16.82	26.70	21	.157
Cow manure extract	8.88	16.92	25.80	23	.163
Cow manure extract, sterilized	7.78	15.96	23.74	18	.158

The largest yields were obtained by applying extracts of sheep, horse, and liquid manure that had not been previously sterilized; in case of cow manure the result was less marked. It is evident, therefore, that sheep, horse, and liquid manure possess a fertilizing effect aside from the quantities of fertilizer constituents contained in them, viz, through the activity of bacteria that are found therein.—F. W. WOLL.

Analyses of commercial fertilizers, H. J. WHEELER, B. L. HARTWELL, and C. F. KENYON (*Rhode Island Sta. Bul. 56, pp. 9*).—Tabulated analyses and valuations of 46 samples of fertilizers.

Commercial fertilizers, M. A. SCOVELL, A. M. PETER, and H. E. CURTIS (*Kentucky Sta. Bul. 82, pp. 32*).—This includes a summary of the provisions of the fertilizer law, notes on the selection of fertilizers, and a list of all the fertilizers entered for sale in the State up to the time of the publication of the bulletin, July, 1899, with guaranteed analyses.

Tobacco as manure, G. FALIÈS (*Tabac, 19 (1899), No. 354, pp. 23*).—Analyses are given of the composted waste products obtained from tobacco manufacturing establishments which show this material to be richer in fertilizing elements than barnyard manure.

Dangerous sulphate of ammonia (*Bul. Agr. [Brussels], 15 (1899), No. 4, pp. 251, 252*).—Analyses are reported of 3 samples of sulphate of ammonia containing over 7 per cent of free acid (calculated as sulphuric).

FIELD CROPS.

Report of the experimentalist, C. A. ZAVITZ (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 119–183, figs. 2*).—The details and results of culture experiments and variety tests with imported and home-grown grain, field roots, silage, and forage crops carried on in 1898 are given, in continuation of similar work previously reported (E. S. R., 10, p. 237).

The experimental plats for all crops were $\frac{1}{100}$ acre in size. In the variety tests with grains, seed was sown broadcast at the rate of 100 lbs. per acre.

Barley (pp. 122–126, 141, 142–148).—Nineteen two-rowed, 15 six-rowed, and 11 hulless varieties of barley were tested. The average yield for the two-rowed and six-rowed varieties was 66.25 bu. per acre, or more than 27 bu. per acre greater than in 1897. The average yield of the hulless varieties was 47 bu. per acre, or nearly 24 bu. per acre greater than in 1897. The weight of the different varieties in 1898 was also high; that of the two rowed and six-rowed varieties having an average of 53.3 lbs. per measured bushel and that of the hulless variety, an average of 63 lbs. per bushel. Mandscheuri, a six-rowed variety, gave the largest total yield of all the varieties tested in 1898, 77.6 bu. per acre. This variety has also given the best average yield of 8 varieties tested for 10 years, 65.02 bu. Two-rowed Italian, Jarman Selected Beardless, Kinna Kulla, and Vermont Champion gave the best returns among the two rowed varieties tested, all yielding more than 68 bu. per acre. Hog, Purple, Guy Male, and Black Hulless gave the best yields of the hulless varieties, each exceeding 50 bu. per acre. In a test of seeding barley broadcast and with a seed drill on 6 different dates, the best average results were obtained by seeding with the drill April 22–25. Seeding on these dates has also given the best results for the whole 4 years of the test. Winter barley has not proven a reliable crop at the station.

Peas (pp. 126–130, 148).—Fifty-two varieties were tested, 41 of which have been grown on the experimental grounds 5 years in succession. The data for the yields of grain and straw and percentage of grain injured by weevils are tabulated. The best yields in 1898 were given by Waterloo, Early Fame, White Wonder, and Tall White Marrowfat, in the order named, each yielding over 30 bu. per acre. White Wonder stands at the head of the varieties tested for 8 years, having an average grain yield of more than 37 bu. per acre. This variety is considered especially desirable for comparatively rich soils because of its short growth of straw. The Odd Fellow and Mummy varieties have been least subject to weevil attacks. Peas were sown broadcast and in drills on 6 different dates. The best results in 1898 and the best average results for 3 years were obtained from plats sown about April 22 with a drill.

Spring wheat (pp. 130–132, 148).—Data for tests of 48 varieties are recorded. The average yield for all varieties was 32 bu. per acre. The largest yield, 48.29 bu. per acre, was afforded by Wild Goose, followed by Medeah, 42.55 bu., and Herison Bearded, 41.07 bu. per acre. Wild Goose has given the best average yield of 15 varieties tested for 9 years or more—34.13 bu. per acre. Red Fern stood second with an average yield for the same period of 30 bu. per acre. Herison Bearded is considered one of the best milling varieties tested; its average yield for 10 years has been 28 bu. per acre, with an average weight of 62.5 lbs. per bushel. The average difference in yield of seeding wheat broadcast and with a drill has not varied more than 10 lbs. per acre in the 4 years in which this subject has been investigated. Early seeding, April 18–19, has given the best results for 6 different dates tested.

Winter wheat (pp. 132–136).—A summary is given of the data already published in College and Farm Bulletin 108 (E. S. R., 10, p. 63), and, in addition, comparative data showing the pressure required to crush the grain of 48 varieties grown in 1896 and 1898. "The 15 hardest wheats produced an average of 7.2 bu. per acre less than the average of the 15 best-yielding varieties, and 2.9 bu. per acre more than the average of the 15 poorest-yielding varieties." Pride of Genesee and Turkish Red were the hardest wheats tested, each being rated at 100. The first, however, stands 19 in average yield and the second 42 in a test of 48 varieties. As a rule, red wheats have proven harder than white wheats. The hardest varieties usually give low yields and possess light straw.

Oats (pp. 136–140, 142, 148).—Of 91 varieties tested in 1898, Vick American Banner, Poland White, Siberian, Joanette, Improved Besthorne, Holstein Prolific, Probsteier, and Oderbrucker stand at the head of the list, in the order named, with average yields of more than 106 bu. per acre. The Siberian is considered the best all round variety tested, its average grain yield for 10 years having been 82.69 bu. per acre. Joanette has given the best average yields of the black oats, and in cooperative tests on 108 Ontario farms it exceeded Black Tartarian by about 2 bu. per acre. Eleven of the varieties tested in 1898 produced grain averaging upwards of 40 lbs. per measured bushel. The percentage of hull to grain was least with the Joanette variety. Seven varieties produced grain having less than 30 per cent of hull. Oats drilled have given better results for 3 years in succession than oats seeded broadcast, and the best yields and heaviest oats per measured bushel have been obtained from seeding on or about April 22. "After this date there was considerable decrease in quantity and quality of grain." Winter oats have not been successfully grown.

Rye (pp. 140–141).—Three varieties each of spring and winter rye were tested. Dakota Mammoth and Prolific Spring gave the best yields of the spring varieties, each over 35 bu. per acre, and Mammoth Winter and Monster Winter the best of the winter varieties, each yielding more than 57 bu. per acre.

Beans (pp. 142–144).—Thirty-seven varieties were tested. White Wonder has given the best average yield for 2 years in succession, 27.46 bu. per acre. Schofield Pea, Burlingame Medium, Pearce

Improved Tree, and Medium or Navy have given average yields for the same period of from 24 to 25 bu. per acre. The best average yields of varieties tested for 5 years have been made by Medium or Navy, Boston Pea, and Small White Field, an average of a little more than 18 bu. per acre.

Mixed grain (pp. 144, 145).—Eleven combinations of oats, spring wheat, barley, and peas have been tested for 6 years for the production of grain and straw. The best yield of straw in 1898 was obtained from a mixture of peas and oats and the heaviest yield of grain from a mixture of barley and oats. Barley and oats, and barley, peas, and oats have given the heaviest yields of grain for the whole period of the test. The influence exerted by the different grains on the yield of grain is in the following order: Oats, barley, peas, and wheat.

Seed selection (pp. 144–148).—Different qualities of seeds for a number of crops were selected and tested. Large plump seed have given the largest yields and heaviest grain per measured bushel for barley, spring wheat, oats, and peas. Hulled oats gave better yields than light-weight oats. Whole peas gave yields 3 times greater than cracked peas, and in a test of weevily peas only about one-fourth of the infected seeds grew.

Preparation of soil (pp. 149, 150).—Spring grain on potato, turnip, or carrot land gave the best yields on that portion of the plats which were plowed. The quality of the grain, however, was somewhat better on the portion simply cultivated.

Potatoes (pp. 150–159).—The results for 1898 and the average results for 3 years are tabulated for 183 varieties of potatoes. Convoy, Empire State, and Rural New Yorker have produced the largest average yields for this period, all having yielded at the rate of more than 220 bu. per acre. Ninety-one per cent of the crop of Rural New Yorker No. 2, Ohio Jr., Green Mountain, and Boley Northern Spy were marketable. Empire State has given the largest average yield of 39 varieties tested for 7 years in succession, and is considered one of the most substantial varieties grown. In a 3-year test of 11 early varieties, equal portions of which were harvested 9, 12, and 15 weeks after date of seeding, Stray Beauty gave the largest average yield at the first digging, 124 bu. per acre, followed by Early Ohio, 111.98 bu., and Howe Premium, 107.92 bu. per acre. The largest yields for 4 years in succession have been obtained from planting large seed, and this has been true whether whole seed potatoes were being compared or single eye pieces of different sizes. In a test of single pieces weighing 1 oz. each and containing different numbers of eyes, the best yield was obtained from the pieces having the largest number of eyes. Potatoes planted in rows 26.4 in. apart and 12 in. distant in the row and given flat cultivation gave better yields than potatoes planted in rows 33 in. apart and 33 in. distant in the row and cultivated either flat or hilled. Potatoes cut and planted the same day have given better yields for 4 years in succession than when planted 4 days after being cut.

Mangels (pp. 159, 160).—Jarman Selected Golden Tankard and Jarman Giant Intermediate gave the best yields in 1898 in a test of 67 varieties of mangels, the yield in each case being at the rate of more than 34 tons per acre. Among 27 varieties tested for 8 years Evans Improved Mammoth Saw Log, Simmer Improved Mammoth Long Red, Steele Long Red Selected, and Carter Champion Yellow Intermediate have given the best results, with yields in each instance averaging more than 23 tons per acre.

Sugar beets (p. 161).—Fourteen varieties of sugar beets were grown for feeding purposes. Lane Improved gave the largest yield in 1898. It has also given the best average yields of 8 varieties tested for 7 years in succession, a little more than 19 tons per acre. Of the varieties tested for a less number of years Green Top White and New Danish Improved, each with yields upward of 20 tons per acre, stand at the head.

Carrots (pp. 162, 163).—The best yields in 21 varieties tested for 7 years have been made by Pierce Improved Half Long, 29.1 tons per acre; Mastodon, 28.44 tons per acre, and Steele Improved Short, 28.41 tons per acre. In all, tests of 51 varieties are reported, but these average yields have in no instance been exceeded.

Kohl-rabi (pp. 163, 164).—Early White Vienna gave the best yield in 6 varieties tested in 1898, 23.95 tons per acre. The largest average yield for 2 years has been made by Large White, 25.70 tons per acre, and Early White Vienna, 25.45 tons per acre.

Fall turnips (pp. 164, 165).—A special feature of this test was the determination of the rot-resisting quality of 46 varieties. Varieties least subject to rot were Cow Horn, Yellowstone, Early American, Purple Top, White Egg, Jersey Navet, and Jersey Lily, in the order named.

Root seeding and culture (pp. 165–169).—Seeding mangels, carrots, sugar beets, and Swedish turnips 1 in. deep has given better results in every instance than seeding 2, 3, and 4 in. deep; and large plump seed has given better yields than medium sized or small seed. Thinning when the plants were 1½ to 2 in. high has been found a better practice than waiting until the plants have attained a height of 8 to 10 in. The average yields from flat culture have been slightly in excess of the yields obtained when ridge culture was practiced; and nitrate of soda has proven a more efficient fertilizer for roots than muriate of potash, superphosphate, or a complete fertilizer.

Millet (169, 170).—Japanese millet (*Panicum miliaceum*) with a hay crop of 5.89 tons has given the highest average yield of 19 varieties, 14 of which have been tested for 4 years in succession. The largest average yields of seed per acre were produced by Hungarian Grass, California, Siberian, and Early Harvest.

Besides these crops data are also given of tests of 12 varieties of pumpkins and squashes, 3 of sunflowers, 2 of rape, 20 of grasses, 11 grain mixtures for green fodder, 2 grass mixtures for permanent meadows, 6 pea and bean fodder crops, and a few varieties each of kale, cow cabbage, clovers, and other miscellaneous crops. Nitrate of soda has proven the most efficient fertilizer for rape. Subsoiling for this crop has not proven financially profitable. Rape seeds planted from ½ to 1 in. deep produced a greater percentage of plants than when planted deeper.

Cooperative experiments in agriculture, C. A. ZAVITZ (*Ont. Agr. and Expt. Union Rpt. 1898, pp. 14–42*).—This report presents the summarized results of successful experiments made in 1898 and the conclusions drawn from them. Nineteen different experiments, representing nearly all the farm crops grown in Ontario, were conducted by 3,028 farmers, 667 of whom sent in satisfactory reports.

In the fertilizer tests, nitrate of soda and muriate of potash were each applied at the rate of 160 lbs. per acre, and superphosphate at the rate of 320 lbs. The complete fertilizer consisted of 53⅓ lbs. each of nitrate of soda and muriate of potash and 106⅔ lbs. of superphosphate per acre. As in the preceding season, a complete fertilizer proved best for oats, a potash fertilizer for corn, and a nitrogenous fertilizer for mangel-wurzels. The largest average increase in yield per acre attributed to the use of fertilizers was 9.8 bu. for oats, 1.32 tons for corn, and 5.74 tons for mangel-wurzels.

The results of a test of various crops for green fodder showed that grass peas were more productive and better suited for this purpose than crimson clover or vetch. One and one-half bushels of oats and 1 bu. of peas per acre are recommended as a good mixture for the production of green fodder. Among 4 varieties of millet Japanese panicle and Japanese common were the most popular with the experimenters. Four different grasses—tall oat grass, timothy, meadow fescue, and orchard grass, and 4 leguminous crops—mammoth red, common red, and alsike clover, and alfalfa, each mentioned in the order of their productiveness, were tested as hay crops. Of the varieties of buckwheat tested, Japanese, stood first; Silver Hull, second; and Common Grey, third. Spring rye gave a larger yield than either of 3 varieties of spring wheat with which it was compared. Of these varieties of wheat Rio Grande, which has a rather coarse grain, was most productive. Mandscheuri barley has maintained its place at the head of the list of varieties tested for 7 years in succession. The results show that six-rowed varieties of barley are more productive than either the two-rowed or hulless sort. In the comparative tests of oats, Siberian stood first for 4 years; then in 1896 and 1897, Oderbrucker gave the best yield; and in 1898, Siberian again took the lead.

Of 4 leading varieties of peas, Early Briton, the best yielder for 3 years, and Chancellor, were considered the best varieties by the experimenters in 1898. The White Wonder bean was found more productive than the California pea bean. Evans Improved Mammoth Saw Log mangel-wurzel has given the highest average yield per acre, 35.1 tons, among the varieties grown for 3 years. Fall turnips gave larger yields than swedes. Purple Top Mammoth turnips and Hartley Bronze Top swedes are considered the best among the varieties tested. No one variety of corn was found well suited to the entire Province. Mastodon Dent corn produced the largest yield of fodder per acre and appeared to be well suited to southern Ontario; while Mammoth Cuban gave best results in the central and southern parts, Wisconsin Earliest White Dent in the central, and Salzer North Dakota in the northern part. Of the 6 varieties of potatoes used in the test in 1898, American Wonder was the latest and most productive and Stray Beauty the earliest and least productive. The varieties of winter wheat tested, given in the order of their productiveness for the season, were Dawson Golden Chaff, Imperial Amber, Early Genesee Giant, New Columbia, Early Red Clawson, Pride of Genesee, and Poole. Dawson Golden Chaff has been the most highly prized by the experimenters for the past 5 years.

The relation between grain weight and percentage nitrogen content of barley, W. JOHANNSEN (*Chem. Ztg.*, *23* (*1899*), *No. 74*, *p. 275*).—Great variation was found by the author in the nitrogen content of fully developed ripe barley grains from different heads of the same variety of barley grown under like conditions. No definite law relative to this variation was found, but in general the nitrogen content increased with the weight of the kernels. By careful selection, however, for 4 years, a strain of barley was obtained which yielded heavy grains low in nitrogen content.

Improvement in the chemical composition of the corn kernel, C. G. HOPKINS (*Illinois Sta. Bul. 55*, *pp. 205–240*, *figs. 5*).—A report by the station on the chemistry of the corn kernel has been previously noted (E. S. R., 10, p. 844). In the present work the details and results of extensive experiments made to determine the influence of selection in increasing or diminishing the protein and fat content, respectively, of the kernel are given; together with other data on the selection of corn with reference to protein and fat content on the basis of mechanical analysis, and on the proportion of corn germ to kernel.

On the basis of analyses 4 sets of ears were selected for experiment from the 1896 crop of Burr White corn: "(1) A set of 24 ears whose percentage of protein was comparatively high; (2) a set of 12 ears each of which contained a low percentage of protein; (3) a set of 24 ears high in fat content; and (4) a set of 12 ears low in fat content." Each set of ears was planted on separate plats in the spring of 1897. The ears showing the characteristics sought in the highest degree were planted in the middle rows of the plats. At harvest time 10 good ears were selected from each row, except in some instances the outer rows, in each of the 4 plats. From these a composite sample was made by shelling 2 rows lengthwise from each of the 10 ears and mixing the kernels. The average protein or fat content of each row was found by analyzing this composite sample.

Seed for the 1898 crop was obtained by selecting the 4 best ears in each set of 10 ears of the 1897 harvest. These were analyzed individually and the ears again showing the characteristics sought in the highest degree were used for seed. Only seed grown on the "high protein" plat of 1897 was used for planting the "high protein" plat of 1898. Similarly, only seed selected from corn grown on the "low protein" plat was used for replanting this plat the following season, and the same principle was observed in replanting the "high fat" and "low fat" plats. This was for the purpose of retaining the hereditary characteristics of the seed. In 1898, 2 additional plats, arranged to overcome local differences in soil conditions, were added to those already noted. Each plat consisted of 5 rows of 10 hills each. Four kernels of corn were planted in each hill. On the protein plat these consisted of 2 kernels high in protein and 2 low in protein; and on the fat plat, 2 kernels high in fat and 2 low in fat content. The kernels were so placed that the stalk of corn grown from each seed could be known. The crops were gathered and analyzed as in the other plats.

Tables showing the composition of corn planted and of the crop harvested are given for each of the plats, and also the analyses of a large number of individual ears from the different plats showing variations from the corn planted, and these data are discussed at length. A summary is given in the following table:

Composition of corn planted and harvested in 1897 and 1898.

	Crop of 1897.		Crop of 1898.		Crop of 1898 (mixed plats).	
	Planted.	Harvested.	Planted.	Harvested.	Planted.	Harvested.
Protein:	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
High protein plat	12.54	11.10	12.49	11.05	12.60	11.71
Middle rows	12.84	11.12	12.87	11.17	....	....
Low protein plat	9.03	10.55	9.06	10.55	8.66	10.46
Middle rows	8.79	10.21	8.70	10.46	....	....
Fat:						
High fat plat	5.33	4.73	5.20	5.15	5.45	5.08
Middle rows	5.52	4.80	5.38	5.29	....	....

Middle rows	3.99	4.03	3.49	3.85	....	....

> "In the 6 tests the selection of seed corn of high and low protein content has produced differences in the crops varying from 0.50 to 1.25 per cent of protein . . . The selection of seed of high and low fat content has produced differences in the crops varying from 0.67 to 1.45 per cent of fat. The fat content of corn is even more susceptible to the influence of seed selection than is the protein content, doubtless due to the fact that the primary materials from which fat is manufactured, namely, carbon dioxid and water, are usually furnished to the plant in unlimited supply, while the formation of protein is essentially dependent upon the supply of available nitrogen in the soil."

On the basis of a knowledge of the general structure of the corn kernel and the chemical composition of its several parts, the author made investigations to determine the possibility of selecting corn of high or low protein or fat content by purely mechanical means. Longitudinal and cross sections of the kernels were made and the corn classified with reference to protein on the basis of the development of the glutinous layer and with reference to fat content on the basis of the germ development of the kernel. A large number of ears high in protein were mixed with ears low in protein. These were afterwards separated by mechanical means. To test the accuracy of the results, the ears were also analyzed. But few errors in the mechanical separation were made. The method of mechanical analysis was found even more satisfactory when applied to the detection of ears high or low in fat content as shown by the development of the seed germ. The results obtained in the several tests lead to the belief that mechanical analysis of corn kernels with reference to protein or fat content is "both possible and practical."

The question whether the size of the corn kernel bears any special relation to the percentage of protein or fat which it contains was investigated. The weight of kernels from 24 different ears high in protein varied from 0.29 to 0.47 gm. and averaged 0.372 gm. per kernel. The weight of kernels from 16 different ears low in protein varied from 0.275 to 0.41 gm. and averaged 0.337 gm. per kernel. The average weight of kernels from 12 ears of corn high in fat content was 0.345 gm. per kernel and the average weight of kernels from 16 ears of corn low in fat content, 0.42 gm. per kernel. In general, the tendency of corn high in fat content was toward small kernels, and *vice versa*.

To obtain exact data as to the relation between percentage of fat and percentage of germ in the corn kernel, the germs from 80 kernels were removed by soaking in hot water for about 30 minutes. The weight of the whole kernel and also of the separate germs were determined and the results are reported on the basis of dry matter. A synopsis of this data is given in the following table:

Relation of corn germ to kernel.

High in fat				Low in fat.			
Average fat content.	Average weight of kernel	Average weight of germ.	Percentage of germ to kernel.	Average fat content.	Average weight of kernel.	Average weight of germ.	Percentage of germ to kernel.
Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
6.49	0.2652	0.0374	14.11	3.58	0.4631	0.0421	9.10
6.71	.3013	.0373	12.40	3.22	.3181	.0272	8.56
6.08	.3105	.0373	12.01	3.64	.2877	.0238	8.28
5.82	.3419	.0453	13.30	3.32	.3502	.0307	8.73
6.28	.3047	.0394	12.96	3.44	.3548	.309	8.47

"It will be seen that the general relation between the percentage of fat and the percentage of germ in the corn kernel is clearly established."

In conclusion the author states that—

> "All results thus far obtained indicate that it is possible to influence the composition of corn; that by proper selection of seed any of its principal constituents, protein, fat, or carbohydrates, may be increased or decreased. . . .

"While further investigations are necessary and are in progress to determine more accurately the best methods and more definitely the possibilities of improvement in the chemical composition of corn, it is here stated tentatively that . . . any corn grower will be able to select seed and to breed corn to increase or decrease the percentage of any one of its 3 principal chemical constituents. . . .

"It may be stated that improvement in the composition of other parts of the corn plant is under consideration by this station. Plans are made also to investigate other questions relating to this general subject; such as the effect of changes in the chemical composition of corn upon its digestibility, vitality, yield, etc."

Composition of rye grain at different stages of ripeness, N. K. NEDOKUCHAEV (*Izv. Moscow Selsk. Khoz. Inst., 5, (1899), pt. 2, pp. 212-224*).—The composition of rye grains was investigated at 5-day intervals, beginning with the close of the period of flowering and ending with the stage called yellow ripeness. It was found that there was an accumulation of carbohydrates, the soluble forms being transformed into insoluble ones. Proteids accumulated at the expense of other nitrogenous compounds, the latter compounds decreasing in amount with the processes of ripening. The relative amount of asparagin nitrogen compared with the total nitrogen remained constant.—P. FIREMAN.

Australian saltbushes: Results of 18 years' tests—characteristics, propagation, and field experiments; composition and food value, C. H. SHINN and M. E. JAFFA (*California Sta. Bul. 125, pp. 30, pls. 7*).—An account is given of the introduction and increasing culture throughout the State of the different species of saltbushes, more especially *Atriplex semibaccata*, brought into California from Australia; of the tolerance of these plants for dry alkali soils, and of their growth on nonalkali uplands; of their vegetation characteristics, and of the cultural methods practiced in California; together with notes on saltbushes in other countries, and descriptions of some 15 species of Atriplex and of the Pacific Coast Salsolaceæ. Results of seed germination tests, and data as to the composition and fodder value of saltbushes are included in the bulletin.

At the Paso Robles Substation seed of *A. semibaccata*, sown in December on poor arid soil, underlaid by hardpan, gave the following season a production of hay equal to 5½ tons per acre at the first cutting in September. Only 4.25 in. of rain fell during the season. Three cuttings were practicable. The same season and with about the same rainfall the yield of green forage on heavy, dark, nonalkali soil, containing considerable adobe, was at the rate of 30 tons per acre. The plant withstood a temperature of 14° F.

"On land of which the surface foot contains 0.3 per cent of salt the young plant was found to come up easily, but suffered when the salt contents reached nearly 0.8 per cent, or about 31,000 lbs. of salts to the upper acre-foot. Some of the older plants lived well in soils having a total of 92,000 lbs. per acre in a depth of 3 ft., of which 23,000 lbs. was 'black alkali.' Where the surface crust or upper half inch contained 8 per cent of salts the young plants barely kept alive, and when the amount of salts near the surface was 25 per cent they perished. Nevertheless, there are cases at the Tulare Substation, where single plants, under favoring circumstances, obtain root and thrive where the amount of alkali approaches these highest limits."

As to the desirability of the plant for stock feeding, 5 farmers report that stock will not eat it; 8 that stock will eat only a little, and 37 that stock thrive upon it and are very fond of it. *A. semibaccata* is considered the most desirable of the varieties thus far tested in California, both as regards quantity of yield and quality of crop. It is an arid plant and can not endure heavy summer rains or a moist warm climate.

The root system of *A. semibaccata* grown on alkali and nonalkali soils was studied. On dry alkali soils where water was less than 25 ft. from the surface, the roots did not exceed 5 ft. in length and were branched and fibrous. But one main root developed on plants grown on nonalkali upland soil. This was capable of penetrating through hardpan from 2 to 3 ft. thick. The water content to a depth of 6 ft. of different soils on which the saltbush grew was 394 tons per acre on sandy soil, 1,440 on strong alkali soil, and 690 tons on hardpan soil.

Seeding in place is considered preferable to transplanting. On alkali soils the seed is sown early in October on the surface of the soil and firmed but not covered; on arid uplands a slight covering is desirable. In a germination test of covering the seed on nonalkali soil $\frac{1}{8}$, $\frac{1}{4}$, $\frac{3}{8}$, and $\frac{1}{2}$ in. deep, and not covering, the best results, 70 per cent of healthy plants, were secured when the seed was covered $\frac{1}{8}$ in. deep. At a depth of $\frac{1}{2}$ in. only 25 per cent germinated. Unirrigated alkali soils in a region of light rainfall are thought best for producing market seed.

Methods of feeding saltbushes with other fodders and in silage mixtures are suggested. The food value of different species of this plant is shown by analysis to be as follows:

Composition of different saltbushes.

Name and locality.	Moisture.	Pure ash.	Crude protein	Crude fiber	Nitrogen-free extract	Crude fat.

Change in the sugar content of beets stored in warm and cold rooms (*Bl. Zuckerrübenbau, 6 (1899), No. 20, pp. 316, 317; Deut. Landw. Presse, 26 (1899), No. 81, p. 926*).—Experiments were made by B. Schulze at the Breslau experiment and control station to determine the increase in sugar content of sugar beets caused by evaporation in cold and warm storage. Whole sugar beets in cold storage changed scarcely at all in sugar content during a period of 10 days. In warm storage, however, the sugar content had increased 0.6 per cent at the end of 7 days and at the end of 10 days had risen to 1 per cent. In the case of beets cut in half and one-half stored in a cellar having a temperature of 6 to 7° C., and the other half in a heated room having a temperature of from 18 to 20° C., the percentage of sugar in the halves stored in the cellar increased 0.2 per cent in 2 days and 1.3 per cent in 5 days. The percentage in the halves stored in the warm room increased 0.2 in the first 24 hours, 0.8 in 3 days, and 1.7 in 5 days. In another similar series of experiments the half beet stored in the cellar maintained a constant sugar content for 4 days. On the fifth day the percentage had increased 0.5. The half stored in the heated room had increased 0.3 per cent at the end of 2 days and at the end of 5 days 1.1 per cent.

Wheat—varieties, breeding, cultivation, W. M. Hays and A. Boss (*Minnesota Sta. Bul. 62, pp. 321–494, figs. 51, charts 1*).—This bulletin contains a history, with detailed records, of variety, selection, and breeding experiments carried on by the station and substations through a series of years; a discussion of the botanical characteristics of wheat and of the methods employed by the station in breeding wheat; and suggestions regarding field management of wheat in rotations.

Since the beginning of the experiments with wheat by the station in 1888, 552 foreign and home varieties have been tested. Forty-nine of these varieties have been originated at the station, 6 of which were cross-bred wheats. A large number of the varieties tested were soon discarded because of poor yields of grain or grain of inferior quality. About 200 varieties, collected previous to 1894, have been grown in cooperation with the North Dakota Station. In 1897 these had been culled out to 8 varieties, and in order to still better decide between these varieties a small amount of the grain of each was milled and the flour subjected to the color test, gluten test, and bakers' sponge test. As a result of these tests only 4 varieties were retained in 1898 for further experimentation at the Minnesota Station. These were Bolton Blue Stem, Haynes Blue Stem, Power Fife, and Glyndon No. 711, with average yields for 8 seasons of 24 2, 20.6, 20.8, and 20.8 bu. per acre, respectively.

The color test, gluten test, and bakers' sponge test are described in detail, and tables given which show the average yield of wheat per acre, grade, rust resistance, bakers' sponge test, and gluten test of the best 8 out of 200 varieties collected previous to 1894, and of the best Russian and Saunders cross-bred wheats collected from 1893 to 1896. None of the Russian wheats were found equal to Minnesota wheats, and but one of Saunders cross bred wheats has been retained, the variety Preston, which has given an average yield for 3 years of 23.1 bu. per acre.

Fife and Blue Stem varieties of wheat have been found best suited to Minnesota conditions. Six of the best of each of these varieties were compared with each other and with 3 of the best new varieties originated by the station by selection. The average yield for 2 seasons of the Fife varieties was 22 bu., Blue Stem varieties 23.3 bu., and the new varieties 23.6 bu. per acre.

In a comparison of 8 of the best of 31 varieties improved by selection with 4 of the best collected varieties, the average yield for 4 years for the improved varieties was 26.6 bu., and of the collected varieties 23.6 bu. per acre. Two of these varieties, Minnesota No. 169, obtained by selection from Haynes Blue Stem, and Minnesota No. 163, obtained from Glyndon No. 811 in the same manner, have given average yields for 4 years of 28.4 and 27.7 bu. per acre, respectively.

In 1892 some of the best varieties of wheats were crossed either with pollen from different plants of the same variety or from different varieties. The seed resulting from these crosses was sown, the best plants selected, and the seed from these again sown. This process was repeated with a limited number of the best plants until 1897, when twenty-acre plats were grown. The average yield of 3 varieties obtained by crossing different plants of the same variety for 1897 and 1898 was 21.5 bu., and of 3 varieties obtained by crossing different varieties 21.1 bu. per acre.

The best seed wheats are distributed by the station throughout the State to a few of the better farmers in each county who practice rotatation, and to seedsmen. A price for the wheat is charged and a certificate showing the history of the wheat at the station given.

Following the classification of wheat adapted from Haeckel's "The True Grasses," and general remarks on the botany of wheat, some results are given with drawings of investigations on the root and stem development of wheat, and on the opening of the flowers and anthers. The wheat flowers were found to open early in the morning. The different stages in the unfolding and closing of the flowers are shown in a series of 10 sketches in the case of a blossom which commenced unfolding at 4.45 a. m. and closed at 5.18 a. m.

The method of breeding wheat employed by the station is discussed at length. Charts showing the variation in height of plant, grade of grain, etc., in newly bred wheats are added and details given of planting, selecting, harvesting, and keeping notes. Plans for a wheat crop in six-year and three-year rotations are shown by the aid of diagrams, and suggestions given for the field culture of wheat.

The manuring of potatoes (*Jour. Bd. Agr.* [*London*], *6* (*1899*), *No. 2, pp. 169–172*).—Results are reported of experiments made at different agricultural colleges in Great Britain to determine the effect on the crop of varying quantities of commercial fertilizers, used alone or in combination with barnyard manure. Plats were fertilized with 4, 8, and 12 cwt., respectively, of complete fertilizers (composition not given) combined with 9 tons of barnyard manure in each instance. The increase in the yield of potatoes from this treatment was not in proportion to the increase in the commercial fertilizers applied, and the experiment was financially unprofitable when more than 400 cwt. of commercial fertilizer per acre was employed. Similarly in another experiment a dressing of 10 tons of barnyard manure per acre gave a large increase in yield of potatoes over unmanured plats, but increasing the amount of barnyard manure or fertilizer did not give a proportionally greater profitable yield.

A test was made of the partial substitution of commercial fertilizers for barnyard manure in growing potatoes. Certain plats received 20 and 10 tons of barnyard manure per acre, respectively, while a third plat received 10 tons of barnyard manure and 625 lbs. of a complete commercial fertilizer. The yields of potatoes on the third plat were greater than on the plats fertilized with 10 tons of barnyard manure alone, but not quite so good as yields on the plat receiving 20 tons. The experiment is held to show "that properly proportioned dressings of artificial manures are capable of forming perfectly adequate and effective substitutes for 10 tons of barnyard manure, and that greater profit can be made by growing potatoes with such artificials combined with a moderate amount of dung than by applying large quantities of barnyard manure alone."

In other experiments, in which one of the three essential ingredients was regularly omitted from the commercial fertilizers used in connection with barnyard manure on potatoes, the greatest diminution of crop occurred with the omission of the potash, and of the different forms of potash the poorest results were obtained with kainit and the best with muriate of potash.

Manuring of pastures (*Jour. Bd. Agr.* [*London*], *6* (*1899*), *No. 2, pp. 208–210*).—In experiments on the use of different fertilizers on meadows in 4 counties of England, the best results with regard to both bulk and quality were obtained with the use of phosphatic manures, and basic slag has proved the most suitable form. With this fertilizer good results were obtained 5 years after its application. On chalk and calcareous soils, however, superphosphate was quicker in its action and thought to be more economical than basic slag. Potash manures were especially valuable on light soils. They "greatly improved the quality of the herbage and developed leguminous plants." Nitrogenous manures, such as nitrate of soda and sulphate of ammonia, while increasing the weight of the crop the first year tended to make the pasture coarser, and this was true whether the pastures were grazed or mown. Common salt usually gave negative results, and the general belief that its use makes pastures finer was not supported in these tests. Lime gave good results in but few instances. Basic slag gave all the results usually attributed to lime and at much less cost. Barnyard manure was found most beneficial on light soils. Phosphatic and potash manures both are advised to be used with barnyard manures in order to counteract the tendency of the latter to produce a coarse herbage. The best time of application of phosphatic and potash manures for either hay or pasture land is thought to be in the autumn or early winter when it should be thoroughly harrowed into the soil. "This harrowing enables the manures to become effective more quickly and at the same time promotes the growth of finer herbage by removing the coarse fogg [aftermath] which is apt to accumulate on the surface of most pastures."

Quantities of nitrogen for grass, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Bul. 57, pp. 13–17*).—Three permanent experimental plats which had been devoted chiefly to the growth of leguminous crops and which had received annual applications of muriate of potash and acid phosphate (13 to 14 per cent of available phosphoric acid) at the rate of 180 and 1,200 lbs. respectively, since 1893, were seeded in 1897 with a mixture composed of 7.5 lbs. of common red clover, 15 lbs. of timothy (*Phleum pratense*), and 7.5 lbs. of redtop (*Agrostis vulgaris*). All the plats were limed the same season with air-slaked lime at the rate of 1 ton per acre. One plat had received no nitrogen for 15 to 20 years; another had received annually from 1893 to 1899 150 lbs. of nitrate of soda per acre, and a third 450 lbs. of nitrate of soda per acre for the same period. The yield of hay on these plats in 1899, cost of the fertilizers applied, estimated valuation of the crop, and resulting profits are tabulated for each plat and the different phases of the experiment discussed.

The total yield from the plat which had received no nitrogen fertilizer was at the rate of 5,075 lbs. of hay per acre, made up almost entirely of clover. The total yield of the plat which had received 150 lbs. of nitrate of soda per acre yearly was at the rate of 6,300 lbs. of hay per acre. The first cutting from this plat consisted of about ⅓ clover and ⅔ timothy and redtop; the second cutting was ¾ clover. On the plat which had received nitrate of soda at the rate of 450 lbs. per acre the total yield was 6,913 lbs. of hay. Of this amount "nearly all of the first crop and about ¾ of the second one consisted of redtop and timothy hay."

The data show that the addition of the nitrate of soda, while of no special benefit to clover, greatly aided the growth of timothy and redtop, and is for these crops a valuable fertilizer.

Estimating the value of the manures at $42 per ton for muriate of potash, $40 for nitrate of soda, and $14 for acid phosphate, the profits from the different plats were as follows: First plat, no nitrogen, $6.09; second plat, 150 lbs. of nitrate of soda per acre, $14.34, and the third plat, 450 lbs. nitrate of soda per acre, $19.62.

Financial gain from liming grass land, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Bul. 58, pp. 21–26, fig. 1*).—Data are given for the yields of grass grown for 4 years in succession on limed and unlimed plats which had received the same amounts each year of nitrate of soda and muriate of potash. The same money worth of different forms of phosphoric acid had been used on the different plats in the beginning of the experiment, but owing to great variations in price this was later changed so that in 1899 the crop on each plat had received practically the same amount of phosphoric acid. The limed plats received but one application of lime. This was applied at the rate of 1 ton per acre in 1894. Corn was grown in both series of plats in 1894 and oats in 1895. The use of the lime increased the yield of corn stover on every plat and also the yield of grain, except on plats which had received raw alumina phosphates or floats. The oat crop in 1895 lodged badly, and the data are given merely as a matter of historical completeness. The grass crops of 1896 to 1899 were most benefited by the application of lime. In general, the plats receiving superphosphates were more benefited by lime than those receiving unacidulated forms of phosphate of lime. The author estimates the financial value of the increase of the limed over the unlimed plats to be from $27.09 on the plat fertilized with basic slag meal to $62.35 on the plat which had received ignited alumina phosphate, while the average financial gain for all the limed plats was $45.10. The limed plat which had received no phosphoric acid whatever gave a financial profit second only to the plat fertilized with ignited alumina phosphate, $55.81 per acre.

Report of the farm superintendent, W. M. RENNIE (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 185–198*).—Report on general improvements made during the year with notes on wheat, oats, barley, peas, corn, and potatoes grown and on the preparation of the seed beds for grain and roots. A report on some feeding experiments is noted elsewhere in this issue (p. 672).

Investigations on the influence of cultivation on the productiveness of soils, E. WOLLNY (*Forsch. Agr. Phys. [Wollny], 20 (1898), No. 3, pp. 231-289*).

Cultivation of alfalfa, G. D'UTRA (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 3, pp. 140-157*).

Experiments with lucern (*Deut. Landw. Presse, 26 (1899), No. 90, pp. 1017, 1018*).—Experiments with fertilizers were made on alfalfa grown for the fourth year on land which contained 0.32 per cent of potash in the upper soil and 0.098 per cent of potash in the subsoil. Thomas slag was used alone on one plat, Thomas slag combined with kainit on another, and Thomas slag, kainit, and gypsum on a third. Increased yields were secured in every instance, but the best and most profitable results were secured on the plat manured with all 3 fertilizers applied in the proportion of 600 kg. of Thomas slag, 1,000 kg. kainit, and 1,000 kg. of gypsum.

Concerning the means of growing barley for brewing of low nitrogen content on light soils, T. REMY (*Deut. Landw. Presse, 26 (1899), Nos. 91, pp. 1030, 1031; 92, pp. 1038, 1039*).—Discussion based on work by the author previously noted (E. S. R., 11, p. 531).

Analyses of barley of the 1899 harvest, A. LANG (*Ztschr. Gesam. Brauw., 22 (1899), p. 515; abs. in Chem. Ztg., 23 (1899), No. 82, Repert., p. 293*).—Analyses of samples from a number of different provinces.

Fertilizer experiment with barley, A. SCHILLING (*Ztschr. Landw. Ver. Hessen, 1899, No. 42, pp. 544, 545*).

Improvement in the chemical composition of the corn kernel, C. G. HOPKINS (*Jour. Amer. Chem. Soc., 21 (1899), No. 11, pp. 1039-1057, pls. 2*).—A shorter account of an investigation reported in Illinois Station Bul. 55 (see p. 633).

Cotton culture (*New York: German Kali Works, 1899, pp. 90, figs. 20*).—"The object of this handbook is to present, in convenient form, various details, facts, and reports of improved methods of growing cotton profitably." Methods of cotton culture, and the injurious diseases and insects affecting cotton are given. The appendix contains useful information on fertilizers.

The harmful effects of lime on lupines, ADLER (*Ber. Landw. Vers. Stat. Jena, 1898, pp. 20, 21*).—Different quantities of lime were added to 5 varieties of lupines grown in separate pots. Yellow lupine, black lupine, blue lupine (*Lupinus angustifolius*), and *Lupinus angustifolius leucospermus* all gave decreased yields in the limed pots, though not in proportion to the amount of lime applied. White lupine (*L. albus*) gave largely increased yields in the limed pots.

Study on the development of the sugar beet, L. GESCHWIND (*Bul. Assoc. Chim. Sucr. et Distill., 17 (1899), No. 3, pp. 217-236, figs. 11*).

Experiments with sugar beets, F. DESPREZ (*Jour. Agr. Prat., 1899, II, No. 49, p. 818*).—Data on the yield and sugar content of beets harvested at different dates. The best yields and largest sugar content were given by the harvests between October 21 and November 18.

Fertilizer experiments in Russia, F. LUBANSKI (*Bl. Zuckerrübenbau, 6 (1899), No. 22, pp. 343-347*).—Fertilizer experiments on sugar beets with nitrate of soda, superphosphate, kainit, lime, and the residue resulting from the final separation of sugar from molasses.

Record of experiments with some varieties of sugar cane imported into St. Croix from Hope gardens, Jamaica, C. DAHL and J. ARENDRUP (*Sugar, 12 (1899), No. 1, pp. 3-7*).—A test of varieties giving composition of juice and number of pounds of sugar produced per acre.

Seedling sugar canes, crop 1899 (*Bul. Roy. Bot. Gard. Trinidad, 1899, No. 21, pp. 221, 222*).—Analyses with reference to sugar content and percentage purity are given for 39 of the best canes grown in the 1899 crop. Nine canes contained more than 20 per cent of sucrose, 18 exceeded 19 per cent, and 13 exceeded 18 per cent. The endeavor to obtain a cane which will yield an average of 20 per cent of sucrose and thus maintain the supremacy of cane over the beet sugar industry is thought to be in a fair way of realization.

The daily root work of cane, A. DE VILLÈLE (*Rev. Agr. Réunion, 5 (1899), No. 9, pp. 399-410, dgms. 3*).—The composition of cane grown on fertilized and unfertilized soil was studied. The analyses of leaves, stalks, and roots were made at a number of periods intermediate between 21 and 245 days from date of planting and with especial reference to nitrogen, potash, and phosphoric acid absorption. The daily root work of the canes for different periods was found by dividing the amount of these elements absorbed by the number of days from date of planting.

Culture of sunflowers in Russia (*Mitt. Deut. Landw. Gesell., 14 (1899), No. 22, Sup., pp. 133-136*).

Light and heavy seeds for tobacco, TRABUT (*Gouv. Gen. Algeria, Serv. Bot. Bul. 17 (1898), pp. 4, figs. 3*).—Experiments by the author demonstrated that light tobacco seeds produced plants which developed slower, tended to flower before sufficient development had taken place, and produced a plant less green in color and weighing scarcely half that of plants grown from heavy seeds. He advises that tobacco seeds intended for planting be thrown into water and thoroughly agitated. The seeds which float should be thrown away and the remainder used for seeding the crop.

Virginia tobacco in São Paulo, G. D'UTRA (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 3, pp. 121-130*).

Tobacco cultivation and curing, J. C. ESPIN (*Bul. Bot. Dept. Jamaica, n. ser., 6 (1899), No. 10, pp. 145-158*).—Article intended as a practical guide for all the different operations necessary in the culture, curing, and handling of tobacco as practiced in the West Indies.

Wheat lands of Canada, S. C. D. ROPER (*Pop. Sci. Mo., 55 (1899), No. 6. pp. 766-777*).

Growing wheat and flax together (*North Dakota Farm and Fireside, 2 (1899), No. 11, pp. 4, 5*).—The profitableness of growing these crops together as shown by actual yields is discussed.

How shall meadows be fertilized? J. KÖNIG and E. HASELHOFF (*Fühling's Landw. Ztg., 48 (1899), No. 22, pp. 841-848; Landw. Wchnschr. Prov. Saxony, 1 (1899), Nos. 33, pp. 385, 386; 34, pp. 397-399*).—Results of experiments with different fertilizers on moor, clay, lime, and sandy soils.

Experiments with commercial fertilizers on meadow lands, M. JANS (*Landw. Wchnbl. Schleswig-Holstein, 49 (1899), No. 48, pp. 887-889*).

A new method of ensiling, F. NOACK (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 3, pp. 162, 163*).

HORTICULTURE.

Report of the horticulturist, H. L. HUTT (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 93-108*).—Variety tests were made of red raspberries, black raspberries, blackberries, currants, gooseberries, strawberries, and tomatoes. In testing grapes "it has been found that varieties ripening with or later than the Concord do not mature a crop in more than one season out of four or five." The most desirable or promising among many varieties of geranium, coleus, gladioli, and chrysanthemum are mentioned.

A brief report is made on a forestry experiment conducted in cooperation with the Division of Forestry of this Department. Seeds of 9 species of forest trees were received from 14 States for experimental planting. The percentage of germination was poor owing probably to too great drying of the seeds before planting. A tabular statement is made of the height of the seedlings at the end of the first and second season's growth.

Forcing rhubarb, F. W. CARD (*Rhode Island Sta. Bul. 55, pp. 88–96, figs. 4*).—Six rhubarb plants taken from a lot which had been dug before the ground was frozen (December 6) were planted in the greenhouse, 3 in practically full sunlight and 3 in a warm place under the bench with sides and ends closed to keep them in darkness. On December 17 other plants were added to both groups from the remaining roots which had been left in the field and allowed to become thoroughly frozen. The plants were examined January 6. Those brought in before freezing had made but little growth, some of the plants in full sunlight being almost dormant. The frozen plants, however, were making rapid growth, especially those in the dark, where many vigorous stalks had started, some of which had attained a length of from 12 to 20 in. Of this growth the most was stalk, but little leaf being developed. The product from these stalks was delicately colored and of good flavor. The plants under the bench were removed February 27 and those above March 6.

On January 9, 5 large plants and 3 small ones which had been dug December 6 and left in the open field, subject "to repeated freezing and thawing, rain and snow," were placed in one corner of the cellar of a dwelling house and kept screened from the light. The cellar had an average temperature of about 40° F. and the soil was wet and muddy. At the same time similarly treated roots were placed under the greenhouse bench beside those put in earlier. Ten days later the plants under the greenhouse bench had started into good growth, many stalks being 3 to 4 in. long, while the roots in the dwelling-house cellar had remained practically dormant. These roots had only just pushed through the soil 3 weeks after date of planting and gave their first product March 11, or nearly 9 weeks from date of planting. The plants under the bench were removed March 17.

The total yield from the different lots and average yield per plant are shown in the following table:

Rhubarb forced in light and in darkness before and after freezing.

Condition of plants set.	Light.			Darkness.		
	Number of plants grown.	Total yield.	Average per plant.	Number of plants grown.	Total yield.	Average per plant.
		Pounds.	*Pounds.*		*Pounds.*	*Pounds.*
Not frozen	8	0.08	0.027	3	5.43	1.81
Frozen	9	41.06	4.56	7	43.47	6.21
Repeatedly frozen, grown in the greenhouse	....	....	....	8	41.34	5.17
Repeatedly frozen, grown in the cellar.	....	....	....	8	107.00	13.38

The yields are believed to show the value of allowing plants to freeze before attempting to force them and of growing them in darkness rather than in light.

The time required for the development of the different lots may be noted as follows: Unfrozen plants grown in light gave practically no yield at any time. Those grown in darkness yielded the bulk of their crop more than 2 months after being placed in position. Frozen plants grown in light gave their first large picking 8 weeks after being brought in and the second 2 weeks later, the bulk having been taken at these 2 times. Plants frozen and grown in darkness yielded several pounds 17 days after being brought in and the bulk within the next 2 weeks, but continued to yield something for a period of 6 weeks. Plants repeatedly frozen and grown in darkness in the greenhouse yielded 1 lb. per plant 3 weeks from the time they were brought in. They gave their heaviest yield at the end of 6 weeks and a good yield at 8 weeks. Similarly treated plants, placed in a cool cellar, gave their first product a little more than 2 months after planting and continued to yield for 2 months longer. Photographs are given of the products at different stages of growth, and the large development of waste product in leaves in plants grown in light over plants grown in darkness is brought out.

The cooking qualities of plants grown in darkness and in light were tested. Sauce made from stalks grown in the light was less attractive in appearance than that made from stalks grown in darkness. Its flavor, however, was more pronounced. The attractiveness of the sauce seems to depend upon the method of cooking and the color of the stalk, while the color of the stalk is influenced by conditions under which it grows. Thus stalks grown in darkness were more delicately colored than those grown in the light, and stalks from the cooler dwelling-house cellar were much brighter and more highly colored than those grown in the warmer position beneath the greenhouse bench. Hot water applied to the stalks at first seemed to extract much of the color. Sugar should be added to the sauce after it has cooked rather than before, as otherwise "the acid present in the rhubarb acts upon the sugar, changing it into glucose, and the higher the temperature the more rapidly does this change go on."

Fertilizer experiments with vegetables, R. OTTO (*Gartenflora, 48 (1899), No. 21, pp. 563–570*).—The effects of compost and stable manure alone, and of various commercial fertilizers alone and in different combinations, on turnips, head lettuce, and kohl-rabi were studied in a series of plat experiments. The largest total yields and the heaviest and best plants were obtained in every instance from the plats fertilized with stable manure. Compost stood second in the case of kohlrabi, and, with regard to size, of both turnips and lettuce. The second best yield of lettuce was obtained with kainit and superphosphate, and the second best yield of turnips with nitrate of soda.

The chemical composition of the kohl-rabi on the plats differently fertilized was determined. The greatest amount of dry matter, 13.81 per cent in the fresh heads, was found in the plants which had been fertilized with superphosphate. The lowest amount, 8.24 per cent, was found in the plants which had received stable manure. The highest nitrogen content, 5.42 per cent, was found in the plants fertilized with stable manure. In general the nitrogen content was highest in the plants which received nitrogenous manures, and lowest where only phosphate or potash manures were applied.

The ash content was greatest in plants fertilized with superphosphate, 11.19 per cent, and kainit, 11.07 per cent, and lowest in the plants which had received nitrate of soda, 8.76 per cent.

Some reports from trial stations on new orchard fruits and shrubs, J. L. BUDD (*Iowa Sta. Bul. 41, pp. 65–129*).—A report is given on the value of a number of varieties of fruits, ornamental trees, and shrubs which were obtained from central Asia, northwest China and Mongolia, and the Steppes of eastern Europe and planted at the station and sent out for trial. The data collected is in the form of replies to a circular of inquiry sent out by the station in November, 1898, to persons to whom material had been distributed between the years 1883 and 1894. The replies deal with the development, hardiness, and worth of apples grown in 65 different localities, pears in 24, cherries in 81, plums in 68, peaches in 39, and shrubs in 26. These localities differ widely in elevations, soils, and exposure, and extend over a wide range of latitude and longitude.

Results thus far secured attest the "remarkable hardiness of many of the east European trees and shrubs," and it is believed by the author that "their introduction will lead to natural and artificial crossing that will improve the fruits in size and quality and yet retain a large part of the hardiness of the mothers."

A contribution to the study of the culture of the olive, B. FLAMINIO (*Rev. Cult. Coloniales, 4 (1899), No. 30, pp. 323–332*).—This article is a translation of a bulletin of the experimental oil mill at Corenzo, Italy, and relates principally to a revision of fertilizer formulas for the olive.

The first part is devoted to a review and criticism of the work of previous investigators on the subject. Analyses are reported showing the ratio of pit to pulp, percentage composition, ash analyses of the wood and leaves removed in pruning, and whole fruit and different parts of the fruit. The facts that branches differ much in composition at different ages and that there is a great difference in the ratios between wood and bark in fresh and air-dried wood were taken into consideration in computing fertilizer formulas for the olive, with results differing materially from those of previous investigators. The relation between the weights of the green wood and bark was found to vary in the branches ordinarily removed in pruning, according to the age. In the case of branches only 1 or 2 years old the ratio of green wood to bark was 1.14:1, while in the case of branches 6 years old it was 6:1. These ratios become 1.15:2 and 8.7:2 for the air-dry substances, and the difference between them increases in proportion as the branch increases in size. The composition of the ash of wood removed in pruning and the leaves and fruit of the olive as determined by the author was as follows:

Composition of the ash of pruning wood, leaves, and fruit of the olive.

Ash constituents.	Wood.	Leaves.	Fruit.
	Per cent.	*Per cent.*	*Per cent.*
Potash	20.557	18.680	56.299
Phosphoric acid	15.386	7.676	6.554
Soda	11.376	8.510	4.828
Lime	30.940	35.639	5.708
Other mineral substances	21.741	29.495	26.611
	100.000	100.000	100.000

To make practical application of the above results, the fertilizer requirement of an orchard of 470 trees was estimated. In this orchard there were removed on the average each year by pruning 1,238 kg. of wood and 228 kg. of leaves. To this was added the losses from all other causes, which are estimated at one-sixth of the loss by pruning or a total loss of 1,445 kg. of wood and 226 kg. of leaves. The average yield of fruit per hectare per year is estimated to be 3,150 kg. From these figures, fertilizer constituents removed from a hectare in a year are computed to be as follows:

Fertilizer requirements of olives per hectare.

Fertilizer constituents.	Wood.	Leaves.	Fruit.	Total.
	Kgs.	*Kgs.*	*Kgs.*	*Kgs.*
Nitrogen	10.943	2.683	14.244	27.870
Potash	5 645	1.503	30.041	37.189
Phosphoric acid	4.226	0.618	3.496	8.340
Lime	8.500	0.268	3.046	11.814

The above totals are equivalent to about 25 lbs. of nitrogen, 33 lbs. of potash, 7½ lbs. of phosphoric acid, and 10½ lbs. of lime per acre.

Physiological observations on vines acclimated in the Southwest. Influence on the quality of the wine of different methods of pruning, G. HÉRON (*Prog. Agr. et Vit., 16 (1899), No. 38, pp. 338–344*).—In addition to data on the production of must, wine, and the yield per vine of 14 varieties of grapes, which served to demonstrate that the percentage of alcohol in the wines is not necessarily lessened because of an increased production of fruit but may, on the other hand, increase at the same time; a discussion and some details are given of experiments made to determine the alcohol content of wine made from grapes grown at the extremes of fruit branches as compared with bunches gathered from near the base of the vine and intermediate between these two positions; and also to determine the relative value of pruning to permanent cordons, and renewing each year.

Relative to the value of fruit gathered from different portions of the vine for wine making, the results showed that the alcohol content with 9 varieties was 0.44° greater with fruit gathered from near the base of the vine and 0.78° greater with 5 varieties from bunches picked near the extremity of the fruit branches. Vines pruned back to near the stump each year gave a higher alcohol content in the wine than vines trained to permanent cordons.

Fruit preservatives for exhibition purposes, F. C. HARRISON (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 110–115*).—Tests were made of over 25 different mixtures to determine which would give the best results as a preservative of fruits for exhibition purposes. The fruits on which the present report is made had been kept 1 year and 4 months. The mixtures were made up with tap water. The colors of the various preserving liquids are stated and the effect of each on the shape and color of the various fruits is given. The experiments are being continued.

"It seems to be a very hard matter to find a mixture which does not take the color out of soft fruits, like strawberries or raspberries. For the former, coal oil has been used very generally; but we can not speak of it as an ideal mixture, viz, a clear, colorless liquid, which will preserve, for at least a period of one year, the color and shape of the fruit as it was when growing on the tree or bush. All the fruit herein referred to has been judged by the above standard as to color and shape.

"The best mixtures for the different kinds are as follows: For raspberries, formalin 1 cc., glycerin 10 cc., and water 89 cc., but this is not an ideal mixture, as the color of the fruit changes somewhat. For strawberries, formalin 2 cc., potassium alum 4 grains, glycerin 10 cc., and water 100 cc. The only objection to this mixture is the slightly yellowish tint of the liquid; but the fruit in it is of a better color and firmer than fruit pickled in coal oil. For this fruit a saturated solution of common salt makes a fairly good preservative. For red currants, several mixtures are fairly satisfactory. One of the best was 1 gm. of mercuric chlorid, 10 cc. glycerin, and 90 cc water. For white currants, two solutions did well; one with mercuric chlorid alone and the other with mercuric chlorid and common salt. For gooseberries, a number of mixtures are satisfactory; 1 per cent formalin gave very good results, as did also 2 per cent zinc chlorid."

Lessons from the great drought of 1898, E. MAWLEY (*Jour. Roy. Hort. Soc. England, 23 (1899), pt. 2, pp. 127–139, charts 7*).—The effects of garden mulching and watering on the moisture and temperature of the soil are shown by the aid of diagrams and tables.

On plant composition and manurial requirements, G. TRUFFAUT (*Jour. Roy. Hort. Soc. England, 23 (1899), pt. 2, pp. 140–150*).—The composition of 19 different vegetables and the fertilizing elements requisite for the growth of these crops are tabulated and discussed, and notes given on different soils and composts.

Forcing rhubarb, J. HOBSON (*Amer. Gard., 20 (1899), No. 257, p. 798*).—The forcing of rhubarb in cellars, pits, under benches in the greenhouse, in mushroom houses, and in frames heated by steam are considered.

The Jerusalem artichoke (Helianthus tuberosus), R. ZERSCH (*Mitt. Deut. Landw. Gesell., 14 (1899), No. 19, pp. 296, 297*).

Vanilla, R. LÓPEZ Y PARRA (*Bol. Soc. Agr. Mexicana, 23 (1899), Nos. 39, pp. 767–772; 40, pp. 790–794; 41, pp. 809–816; 44, pp. 872–876*).—A discussion of the history, uses, production, and marketing of vanilla beans.

Mushrooms on benches, R. MAXWELL (*Amer. Gard., 20 (1899), No. 255, p. 765, fig. 1*).—Growing mushrooms on top of benches instead of underneath is advocated and directions given for the preparation and care of the beds for this purpose.

Edible fungi (*Lancet [London], 1899, No. 3971, pp. 969, 970*) —A general article on edible and poisonous fungi. The comparatively low food-value of edible fungi is pointed out and their usefulness as condiments is spoken of.

Summer pruning, G. Quinn (*Jour. Agr. and Ind. South Australia, 3 (1899), No. 4, pp. 368-378, figs. 13*).—The subject is illustrated and discussed under the following heads: Disbudding to shape the tree and to reduce the overcrowding of fruit-bearing wood; pinching off terminal points of shoots to temporarily check their extension; shortening in wood which has been left to carry fruit but which has failed to do so either wholly or in part; and fracturing to induce the formation of fruit-bearing spurs.

Stringfellow method of root pruning (*Nat. Nurseryman, 7 (1899), No. 11, pp. 127, 128*).—Brief review of result secured in Oregon and Georgia (E. S. R., 10, p. 1010). Pruning to 3 in. stubs in Oregon has given excellent results with pears, apples, prunes, plums, and cherries on heavy clay soils. The root systems of such pruned trees were especially well formed.

Cooperative fruit testing, H. L. Hutt (*Ontario Agr. and Expt. Union Rpt. 1898, pp. 9-12*).—Report on cooperative fruit tests that have been in progress since 1894. The average yields of red raspberries, black raspberries, blackberries, strawberries, and gooseberries are given with notes on a few varieties of the last 3.

Improvement of the persimmon, J. H. Marion (*Missouri State Hort. Soc. Rpt. 1898, pp. 273-276*).—Fall planting, budding, crown grafting, and cleft grafting of 2-year-old seedlings in the nursery row have proven desirable features in the improvement of persimmons.

Pineapples for profit in Florida and Cuba, E. French (*Amer. Gard., 20 (1899), Nos. 261, pp. 877, 878; 262, pp. 895, 896*).

The currant vine, T. Hardy (*Gard. and Field, 25 (1899), No. 5, pp. 101, 102, figs. 7*).—Complete cultural directions including methods of pruning, training, etc., of Zante currants.

A valuable new strawberry, the Rough Rider, L. J. Farmer (*Amer. Gard., 20 (1899), No. 261, p. 882*).—Notes on the origin and value of this strawberry.

Fifty years' improvement in American grapes, T. V. Munson (*Amer. Gard., 20 (1899), Nos. 246, pp. 620-623, fig. 1; 250, pp. 688-690, fig. 1; 254, pp. 750-752, fig. 1; 261, pp. 868-870, fig. 1*).—A series of articles forming a complete survey of our native grapes, and including a list of the leading families and varieties of grapes originated by the author, showing parentage, color, season, etc.

The use of commercial fertilizers in the culture of the vine, L. Degrully (*Prog. Agr. et Vit., 16 (1899), No. 5, pp. 669-673*).—Some results are given showing the value of commercial manures for vines on 4 sandy hill soils.

A new protection against spring frosts, L. Degrully (*Prog. Agr. et Vit., 16 (1899), No. 49, pp. 637-641, figs. 8*).—A specially prepared paper cover for protecting grapes against early spring frosts is described and methods of wrapping the paper on vines illustrated.

Flower and fruit farming in England, W. E. Bear (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 2, pp. 267-313*).—A thoroughgoing discussion of the development and present status of flower and fruit farming in England, considered as hothouse industries.

The florists' tulip: Its origin, history, and classification, R. Dean (*Amer. Gard., 20 (1899), No. 261, pp. 866-868, figs 3*).

Review of garden clematises, K. C. Davis (*Amer. Gard., 20 (1899), Nos. 257, pp. 803, 804; 260, pp. 846-848, fig. 1*).—Cultural, botanical, and descriptive notes on garden clematises.

The principles and practice of fern culture, W. C. Worsdell (*Gard. Chron., 3. ser., 26 (1899), Nos. 663, p. 201; 664, pp. 220, 221*).—The subjects of temperature, moisture, soil, spore seeding, etc., are considered.

Rock gardens, ponds, and streamlets in our pleasure grounds, F. W. Meyer (*Jour. Roy. Hort. Soc. England, 23 (1899), pt. 2, pp. 78-95*).—The laying out and planting of rock gardens, ponds, and small streams are discussed, and 15 lists given of plants suitable for planting.

Some valuable indexes, W. Miller (*Amer. Gard., 21 (1900), No. 263, p. 6*).—Information is given as to where indexes to a number of horticultural periodicals may be found.

WEEDS—DISEASES OF PLANTS.

The horse nettle and other troublesome weeds in Iowa, L. H. PAMMEL (*Iowa Sta. Bul. 42, pp. 131–140, figs. 3, maps 2*).—Notes are given on the horse nettle (*Solanum carolinense*) which is rapidly spreading throughout the State and becoming one of the most troublesome perennial weeds. Its spread throughout the United States is treated historically, and maps given showing its present known range. It appears that this weed is found from Massachusetts southward to the Gulf and westward to Iowa, Nebraska, Kansas, and Texas. Its methods of propagation are by means of seed, and also its rootstocks. Means for extermination are given, from which it appears that probably the most effective and least expensive method of removing this plant is by smothering it with some rapidly growing crop, such as rape. Planting corn or roots is a method much employed, as the cultivation given greatly reduces the spread of the weed. Cutting and burning the weeds when in advanced stage of growth will prevent the production of seed, and to that extent prevent the spread of the pest.

The other weeds mentioned are the European bindweed or morning-glory (*Convolvulus arvensis*) and *Tribulus terrestris*. Both of these weeds are described at some length. For the first, which is a perennial, the same methods of destruction given for the horse nettle are recommended. The last weed is an annual, and the methods usually employed for the destruction of annual weeds may be adopted against it.

Potato scab, C. R. BALL (*Iowa Sta. Bul. 42, pp. 141, 142*).—A brief report is given upon some experiments conducted for the prevention of potato scab. Soaking the seed tubers in corrosive sublimate solution resulted in a crop about 9 per cent of which were more or less scabby, the check plats giving 31 per cent diseased tubers. Formalin and potassium sulphid were also used with beneficial results, and although some of these treatments tend to reduce the total yield slightly, the increase in larger and cleaner tubers more than compensates for the loss.

Bindweed and rib grass, W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 13, 14, figs. 2*).—Brief notes are given of these two weeds with suggestions for their eradication.

Extirpation of prickly pear, E. PILLANS (*Agr. Jour. Cape Good Hope, 15 (1899), No. 8, pp. 548–551*).—Notes the efficiency of arsenical sprays for the destruction of this pest. The government has aided in this work by supplying the materials, about 1,000 cases of 135 lbs. weight having been supplied.

Apple scab and peach-leaf curl, W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 14–19, figs. 3*).—Popular descriptions are given of these two diseases and of the fungi which cause them, and suggestions offered for their prevention. For the first, spraying with carbonate of copper solution or Bordeaux mixture is recommended, and for the second, thorough pruning together with the application of Bordeaux mixture is said to hold the disease in check.

On the use of copper acetate as a fungicide, E. ROCCA (*Prog. Agr. et Vit. (Éd. L'Est), 20 (1899), No. 51, pp. 710–712*).—By evaporating a mixture of copper acetate and sodium sulphate the author claims an insoluble basic compound of great value as a fungicide is obtained. It is said to be very adhesive, traces being apparent on grape leaves in November that had been sprayed in June.

The bacteria of wine disorders, A. BOUFFARD (*Prog. Agr. et Vit. (Éd. L'Est), 20 (1899), No. 49, pp. 643–646, pl. 1*).

Concerning the effect of molds on arsenic and its compounds, R. ABEL and P. BUTTENBERG (*Ztschr. Hyg. u. Infectionskrank., 32 (1899), No. 3, pp. 449–490*).—The authors claim that the peculiar growth of *Penicillium brevicaule* gives a biological test for the presence of arsenic and its compounds. An extensive bibliography is appended.

ENTOMOLOGY.

Report of the apiarist, R. F. HOLTERMANN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 197–208, figs. 9*).—Experiments were conducted to determine the value of good ventilation and a constant temperature in wintering bees. It was found that any changes in temperature during the time the bees were kept in a wintering cellar caused disturbances among the bees and a consequent loss of vitality. Where the temperature was kept constant the bees were much less active and consumed less of their stores. In some instances strong colonies consumed as little as 4¼ lbs. from November 21 to March 23. The temperature was kept at about 42° F.

No brood is produced in hives which are kept at this constant temperature and are prevented from being disturbed. Considerable brood forming was, however, noticed in hives which were troubled with frequent changes in temperature.

The advantages of an artificial arrangement for delivering heat to the bees during wintering and of a specific means of ventilation are that the air is kept pure, that moisture is removed from the colonies, and that the temperature remains constant.

The records for 53 colonies wintered in the cellar showed an average consumption of 12 lbs. per colony from November 18 to April 3. The author maintains that from his experience bees always suffer considerably from outdoor wintering, provided no special arrangements are made for ventilation and the removal of excess of moisture.

The author figures and describes a swarm catcher which is somewhat like a hopper in shape and into which the bees are allowed to crawl at the time of issuing from the mother hive. The catcher is then stood on end until the bees cluster, and is then opened in front of the hive into which the bees are to be introduced.

Experiments with Carniolan bees showed that they produce an excellent quality of comb honey, but have a tendency to excessive swarming.

Experiments were tried in moving bees to fall pasture, especially to buckwheat fields, and the result showed that if the moving is done with ordinary care the increase in the amount of honey made will more than pay for the trouble of moving.

Report on apicultural experiments, R. F. HOLTERMANN (*Ontario Agr. and Expt. Union Rpt. 1898, pp. 71, 72*).—A brief statement is given of the results obtained by the Experimental Union during the year. It was found that the quantity of base left in a comb was directly in proportion to the thickness of the base of the comb foundation, and that the bees could not be depended upon for thinning. The 5-banded Italian bees are not considered desirable for honey-gathering purposes.

In experiments on the specific gravity of honey it was found that the higher the specific gravity the better the quality and aroma of the honey.

Tabanidæ, and a simple method for destroying them, I. PORCHINSKI (*Selsk. Khoz. i Lyesov., 192 (1899), Mar., pp. 557-573*).—About 100 species of Tabanidæ are known in Russia, of which 60 belong to Tabanus, 18 to Chrysops, 6 to Hæmatopota, and the others to Nemorius, Silvius, Hexatoma, and Pangonia. The more common species are *Tabanus tropicus*, *T. montanus*, *T. luridus*, *Hæmatopota pluvialis*, and *Chrysops relictus*. The larger species produce a buzzing sound in flying and attack any part of the body of the animal, although they seem to prefer the neck and belly. Chrysops flies almost without noise, and in the case of horses, alights preferably near the base of the mane.

Water and forest vegetation furnish the proper conditions for the multiplication of Tabanidæ. Where these conditions are not present, as in the treeless steppes of central Asia, Tabanidæ are not found. The Tabanidæ fasten their dark brown spindle-shaped eggs to the leaves and stems of plants, or in the case of species with aquatic larvæ, to rushes. The eggs are glued together in spherical or flattened masses of from 300 to 400. The larvæ hatch within 9 to 12 days. At this stage the body is elongated and cylindrical, the abdominal rings are furnished with soft warty projections on the ventral surface which assist the larvæ in locomotion. In the majority of species there is a respiratory slit in the terminal abdominal segment, and in aquatic species the last two segments form a respiratory tube.

The larvæ of Tabanidæ are predaceous and feed upon the larvæ of other insects. They have been observed preying upon the larvæ of species of Helops and Rhizotrogus. The larvæ of aquatic species, as, for example, *T. autumnalis* and *Hexatoma bimaculata*, attack fresh water Mollusca.

Bembex is a rather effective enemy of the Tabanidæ. It was observed that the gadflies take water at frequent intervals during the adult stage, by darting down upon the surface of pools. The author, therefore, tried experiments in the destruction of Tabanidæ by covering the pools of water with a film of kerosene. Then, in attempting to take water from these pools, the flies came in contact with the oil and were unable to fly away, or, if they escaped, they died later from the effects of the oil. As the surface of the pools became covered with dead flies, it was found necessary to pour on more oil. The following species were found dead upon the pools: *T. bovinus*, *T. tropicus*, *T. montanus*, *T. luridus*, *T. borealis*, *T. maculicornis*, *Chrysops relictus*, and *C. cæcutiens*. Hæmatopota does not visit the pools, and is therefore not to be destroyed by this method.

Recent work on the San José scale in Illinois, S. A. FORBES (*Illinois Sta. Bul. 56, pp. 241–287, pls. 4*).—This bulletin recounts in detail the work of the entomological department, especially of the field assistants, in locating new areas of infection, inspection of nurseries, insecticide treatment, and distribution of fungus diseases for destroying the San José scale.

The principal apparatus used in spraying was a machine sprayer consisting of a 1-horsepower gasoline engine, 3-cylinder force pump, and double galvanized iron tank with a gasoline heater for making the whale-oil soap solution. The wagon when thus loaded with this apparatus weighed 2,400 lbs. The gasoline in the engine is exploded by an electric spark. The tank is made of heavy galvanized iron and holds 170 gal. Underneath the tank are placed 2 sets of gasoline burners for the purpose of heating the solution. The capacity of the pump is from 2.8 to 4.2 gal. per minute, and the pump will operate against 150 lbs. pressure per square inch.

The insecticides used were whale-oil soap solution, pure kerosene, and kerosene and water mixture. It is estimated that 99 per cent of the San José scale in one orchard in which a large number of trees were sprayed was killed by 2 successive sprayings with whale-oil soap in the fall of 1896 and in the spring of 1897. In one case maple trees were badly damaged by the spray of whale-oil soap. The Forbes scale was destroyed rather effectively, but the scurfy scale was little affected by a winter application of whale-oil soap. Subsequent inspection in the orchard where these spraying experiments were carried out indicated that 9 out of 21 places which were treated were free from the San José scale. Those places, however, in which the scale was completely exterminated were not badly infested. The spraying method can not be depended upon for exterminating the scale where it has had a few years to establish itself. The San José scale can, however, be effectively checked by thorough and repeated spraying with whale oil soap at intervals to be determined by inspection in each case. Whale-oil soap solution was used in the strength of 2 lbs. to the gallon of water. The trees were usually pruned back, and where the bark was rough the trees were scraped.

Experiments were conducted in infecting San José scale with 2 parasitic fungi, *Sphærostilbe coccophila* and a species of Microcera. Infection by means of the first-named species was carried out in 2 ways, by hanging branches upon which were found infected scales in trees infested with the San José scale, and by placing portions of artificial cultures of the fungus in the infested trees. The results obtained from both methods of infection were quite successful, perhaps more markedly so in the case of artificial cultures, but these fungi will probably not be able to control the San José scale without the aid of artificial insecticides.

Some experiments were tried with pure kerosene in the month of June. The results were quite unsatisfactory. If the kerosene was used in sufficient quantity to kill the scales, the trees were badly injured or destroyed. Experiments made with mechanical mixture of kerosene and water showed that mixtures containing 5, 15, and 20 per cent of kerosene did not injure the trees, but also did not kill the scales. A 30 per cent mixture killed nearly all the scales, but did not injure the trees. A few experiments were tried with mixtures of Carboleum, but not enough to warrant any final conclusion.

The scales were found on Ambrosia, Lepidium, and Solanum. Some observations made upon the rate of travel of the young indicated an average rate of 1.1 in. per minute. The only insect enemies mentioned as of much importance are *Pentilia misella* and *Chilocorus bivulnerus*.

Investigations on scale insects upon American fruit, L. REH (*Station für Pflanzenschutz zu Hamburg, 1 (1898–99), pp. 19*).—The author gives detailed notes on the position upon the fruit in which scale insects were found. The notes cover all the more common species of scale insects. It has been stated as a general principle that scale insects establish themselves in a position upon the fruit which offers them protection from the sun and rain. The author found, however, that only 2 species were evidently sensitive to these influences (*Aspidiotus ancylus* and *A. forbesi*), but that in general the distribution of scale insects on fruit is determined by the sensitiveness of the scales.

Of the 262 specimens of *A. ancylus* which the author found, 250 were females and 12 larvæ. Only 17 specimens of *A. forbesi* were found, and these were all males. Of the San José scale, the author discovered 82 males, 354 females, and 259 larvæ. Thirty-three specimens of *A. camelliæ*, all of which were females with one exception, were found. Of the specimens of *Chionaspis furfurus* discovered, 115 were females, 17 males, and 1 larva. Of *A. ancylus* 92.75 per cent were alive. Sixteen of the 17 *A. forbesi* were still alive, and of the San José scale 33 per cent were alive. Upon many apples several species of these scales occurred together, and notes are given of the relative frequency of various combinations.

The author conducted a number of experiments for the purpose of determining the danger from the packing of imported fruit, with the general result that living scales were very seldom found in such material. Experiments were also instituted to determine how long the scale insects would live when removed from the fruit and carefully transported to other fruit or to other situations. The experiments indicate that death usually results within a short period after such removal.

American fruit and its parasites, C. BRICK (*Station für Pflanzenschutz zu Hamburg, 1 (1898–99, pp. 34*).—The author made extensive observations on fruit which was imported from America with reference to determining the extent of its infestation by injurious insects and fungus diseases. Detailed notes are given on the following insects which were found upon apples: *Aspidiotus ancylus, A. camelliæ, A. forbesi, A. perniciosus, Chionaspis furfurus,* and *Mytilaspis pomorum.* Two fungus diseases were observed upon apples, *Venturia inæqualis* and *Leptothyrium pomi.*

Special notes are given on the species of scales found upon the different varieties of apples which were imported from different parts of the United States, Canada, and South America. The San José scale was found on Ben Davis from Virginia, on Newtown Pippins from California, and on pears from California. During the period of the author's observations, San José scales were found in 26 barrels and 582 boxes of apples and in 1 box of pears.

With regard to the extent of infestation, the author states that for the most part it was very slight. He also gives notes on dried American fruit, including apricots, pears, cherries, nectarines, and plums. Some scale insects were found upon such fruit, but in nearly every case the scales were evidently dead.

The estivation of the Chrysomelidæ, W. KOLBE (*Ztschr. Ent., n. ser., 1899, No. 21, pp. 26–37*).—The author made observations upon a large number of species of this family for the purpose of determining to what extent they enter into a summer sleep or resting condition. Among the genera which were studied may be mentioned Phytodecta, Lema, Zeugophora, Agelastica, Gallerucella, and Galeruca. All of these genera were observed to pass through a period of estivation, beginning ordinarily with the month of June and ending with the latter part of August or the first part of September. At this latter date the beetles were usually noticed to be in rather active condition and then later to enter upon their regular hibernation period for the winter.

The author believes that this resting period during the summer and a subsequent short active period during the fall may account for the supposed double-brooded condition of many species which are really single brooded. With species of Phytodecta, it was experimentally determined that no changes in the amount of moisture in the air or in the presence of suitable food material were sufficient to arouse the beetles from their resting condition. In the opinion of the author, the majority of the Chrysomelidæ pass through a period of summer sleep.

Observations on the subject of driving away parasites of plants by means of intraorganic injections, A. BERLESE (*Riv. Patol. Veg., 8 (1899), Nos. 1–6, pp. 166–182, figs. 2*).—Experiments were made chiefly upon living specimens of *Urtica urens*. The roots were kept in a solution of cyanid of potash in the proportion of 5 to 2,000.

The author concludes from a series of experiments that injection or imbibition of substances within the plant must be limited, even as a possibly successful remedy, to insects of a sedentary habit. Other means must be used against the great majority of insects. The method proposed by Perosino is not satisfactory, since even if the desired effect is obtained, it is only temporary. The effects of internal insecticides upon the plants themselves and fruits should be studied more carefully. The roots of plants seem to exercise a sort of selective action and refuse to take up certain substances.

Memorial of life and entomologic work of Joseph Albert Lintner, E. P. FELT (*Bul. New York State Mus., 5 (1899), No. 24, pp. 301–611, pl. 1*).—This bulletin contains a brief biological notice of J. A. Lintner, a list of the species described by him, a bibliography of his entomological publications, and a general index to reports 1 to 13 of the State entomologist of New York.

Bees and how to manage them, A. GALE (*Agr. Gaz. New South Wales, 10 (1899), No. 10, pp. 1092–1098, figs. 2*).—Directions for securing wild swarms of bees from trees.

Prevention of the swarming of bees, R. PINCOT (*L'Apiculteur, 43 (1899), No. 11, pp. 495–500*).

The parthenogenetic origin of drones, W. PAULCKE (*Anat. Anzeiger, 16 (1899), No. 17–18, pp. 474–476, figs. 2*).—The author's results, based on a microscopic study of a large number of eggs, favor the Dzierzon theory.

Observations on the metamorphosis of insects, J. E. V. BOAS (*Zool. Jahrb., Abt. Syst., 12 (1899), No. 4, pp. 385–402, pl. 1, fig. 3*).—This paper reports the study of certain points in the development of *Pyrrhocoris apterus*, Myrmeleon, Cossus, Cetonia, Cimbex, and other insects.

Report on economic entomology for 1898, G. H. CARPENTER (*Reprint from Rpt. Council Roy. Dublin Soc. 1898, pp. 14, figs. 13*).—Notes on *Phyllotreta nemorum, Melolontha vulgaris, Bruchus affinis, Myzus cerasi, M. ribis, Eriocampoides limacina, Bryobia prætiosa, Chermes abietis*, and *Lachnus piceæ*.

Notes on Aphididæ, N. CHOLODKOVSKY (*Zool. Anz., 22 (1899), No. 602, pp. 468–477, figs. 7*).—The author gives descriptive and biological notes on a number of species of plant lice, among which may be mentioned *Chermes funitectus, Lachnus piceæ, L. persicæ, L. maculosis, L. abieticola, L. rosæ, Stomaphis graffii, Callipterus giganteus, Tetraneura ulmi, Phylloxera quercus*, and species of Schizoneura and Mindarus. A number of these species are described as new.

A few of the most noxious insects, W. LOCHHEAD (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 11–13, figs. 4*).—Contains popular notes on *Aphis brassicæ*, tent caterpillar, larch sawfly (*Nematus erichsonii*), and Lecanium sp.

Coccidæ, TRABUT (*Gouv. Gen. Algeria, Serv. Bot. Bul. 19, 1899, pp. 59–74, figs. 24*).—A brief account of the more common and injurious scale insects, with recommendations of the more efficient remedies against them.

The San José scale and other scale insects, and the Indiana nursery inspection law, J. TROOP (*Indiana Sta. Bul. 78, pp. 45–52, figs. 3*).—This bulletin contains brief notes on the San José scale, the oyster-shell bark-louse, the scurfy bark-louse, and the Putnam scale (*Aspidiotus ancylus*). The commonly used insecticides are recommended against these insects. The full text of the nursery inspection law of Indiana is printed with the bulletin.

On the larvæ of certain Aspidiotus species, W. MAY (*Station für Pflanzenschutz zu Hamburg, 1 (1898–99), pp. 5*).—Brief notes on the larvæ of *Aspidiotus perniciosus, A. ancylus, A. camelliæ*, and *A. ostreæformis*.

On the North American species of the subgenera Diaspidiotus and Hemiberlesia of the genus Aspidiotus, W. NEWELL (*Contrib. Dept. Zool. and Ent. Iowa State Col. Agr. and Mech. Arts, 1899, No. 3, pp. 31, pl. 1*).

European scales on fruit, L. REH (*Illus. Ztschr. Ent., 4 (1899), No. 23, p. 361*).—Notes on *Aspidiotus ostreæformis*.

Insect enemies of citrus fruits, E. ARNAO (*La coltivazione degli agrumi. Palermo: A. Reber, 1899, pp. 279–328, figs. 20*).—A general discussion of the insect enemies of these fruits with special reference to species of Aspidiotus, Mytilaspis, Parlatoria, Lecanium, and Dactylopius. The author also reports upon the remedies which have given best results in combating the various insect pests.

Imported pests, G. VERT (*Bol. Soc. Nac. Agr. Brazil, 2. ser., 1899, Nos. 2, pp. 34–39; 3, pp. 67–68; 4, pp. 98–101, figs. 3, pls. 4*).—Brief accounts of San José scale, phylloxera, and *Margarodes vitium*.

Report on the distribution of phylloxera in Austria (*Bericht über die Verbreitung der Reblaus in Österreich im Jahre 1897. Vienna: Imp. Roy. Agr. Min., 1899, pp. 164*).—A detailed statement is given of the extent and spread of infestation by Phylloxera. The use of American stock is recommended and the application of bisulphid of carbon. Various laws and decrees are printed in this report concerning the treatment of vineyards and the spread of phylloxera.

New experiments in the destruction of phylloxera, G. COUANON, J. MICHON, and E. SALMON (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 20, pp. 783, 784*).—Young grapevines were entirely freed from phylloxera by immersion for from 3 to 5 minutes in water at a temperature of 53° C. The vines were uninjured by the hot water treatment, and when planted, exhibited vigorous vegetative growth.

Experiments in destroying phylloxera, LANFREY (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 22, p. 865*).—One kilogram of picric acid was dissolved in 90 liters of water. One liter of this solution was poured about the roots of each vine. It proved a very successful remedy. The months of June, July, and August seemed most opportune for the application of this solution.

Insects injurious to cereals, V. MAYET (*Prog. Agr. et Vit. (Éd. L'Est), 20 (1899), No. 45, pp. 526–536, pl. 1*).—This paper contains an account of the appearance, life-history, habits, natural enemies, and artificial remedies of *Oscinis frit, Chlorops lineata, Cecidomyia destructor*, and *C. tritici.*

The influence of a mild winter upon the first flight of the Geometridæ, NAGEL (*Ztschr. Ent., n. ser., 1899, No. 24, pp. 38, 39*).—The winter of 1898–99 having been especially mild, the author was led to observe the time of flight of the first individuals of certain genera of Geometridæ. It was found that their occurrence was unusually early in the season. The individuals observed were of the genera Hibernia and Phigalia.

Australian case or bag moths, W. W. FROGGATT (*Agr. Gaz. New South Wales, 10 (1899), No. 10, pp. 1085–1091, pl. 1*).—Gives biological notes on the following species: *Metura elongata, Thyridopteryx herrichii, T. hubneri, T. boisduvali, Entometa ignoblis, Clania lewinii, and Oiketicus macleayi.*

The life cycle of the Coccidia and Hæmosporidia, F. SCHAUDINN (*Zool Centbl., 6 (1899), No. 22, pp. 765–783*).—In this article the author has brought together the literature of the subject in an extensive bibliography. A critical examination of the results thus far obtained is presented. The forms of Sporozoa which received most attention are species of Coccidium, Plasmodium, Halteridium, and Proteosoma.

Vaginula slugs, H. TRYON (*Queensland Agr. Jour., 5 (1899), No. 1, pp. 63–70, pl. 1*).—Two species of slugs (*Vaginula hedleyi* and *V. leydigi*) are reported as causing considerable damage to the majority of garden vegetables. The slugs are figured and described. The eggs are deposited under logs or stones in masses of 40 or more. Domestic poultry, birds, toads, and frogs have not been observed to eat the slugs. Tobacco waste and lime spread upon infested ground have a deterrent effect upon the vaginulas. Poisoned bran is also recommended as an artificial remedy. Old boards and wet sacks placed on the ground serve as hiding places for the slugs, and in the daytime they may be found in such situations and easily destroyed.

Agrotis saucia and one of its new forms, W. CASPARI (*Jahrb. Nassauischen Ver. Naturkunde, 52 (1899), pp. 185–201*).

Treatment for the potato beetle, C. A. ZAVITZ (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 157, 158*).—Experiments were conducted upon potatoes with the object of determining the relative efficiency of Paris green in water, Paris green with plaster, and a proprietary insecticide known as "potato bug finish," in the destruction of potato beetle. Tests were carried through 2 years, and the results showed that the best form of insecticide for this insect was Paris green dissolved in water.

Combating the enemies of field crops, V. MORACHEVSKY (*Selsk. Khoz. i Lyesov., 194 (1899), Sept., pp. 445–454*).—A discussion of the depredations of and remedies to be used against the following insects: *Agrotis segetum, A. exclamationis, Anisoplia austriaca*, and the Hessian fly.

Combating the enemies of field crops, V. MORACHEVSKY (*Selsk. Khoz. i Lyesov., 194 (1899), Aug., pp. 193–225*).—This article is occupied with a discussion of the Acrididæ and for the greater part with *Pachytylus migratorius* and *Caloptenus italicus.* Among the remedies which are used in the different provinces of Russia against these insects may be mentioned thorough cultivation and harrowing of the infested lands, burning of straw, crushing the nymphal locusts with various farm implements, the use of ditches, catching the locusts with various contrivances, and infection with *Empusa grylli*.

Crop pests, remedies and spray pumps, G. McCarthy (*Bul. North Carolina State Bd. Agr., 20 (1899) No. 12, pp. 10–25, figs. 6*).—Brief descriptions of a number of injurious insects and fungus diseases, and a spray calendar with directions for making the common insecticides and fungicides.

Fruit protection, E. J. Wickson (*California Fruits and How to Grow Them. San Francisco: Pacific Rural Press, 1900, pp. 434–464, figs. 30*).—A general discussion of the habits, life history, and means of combating the common noxious insects, rabbits, gophers, and birds.

The use of Sporotrichum globuliferum in combating insects, Trabut (*Gouv. Gen. Algeria, Serv. Bot. Bul. 19, 1899, pp. 58, 59, figs. 2*).—Reports the successful application of this fungus in destroying Haltica, Pemphigus, and species of locusts.

A brief report on locust fungus, D. McAlpine (*Agr. Gaz. New South Wales, 10 (1899), No. 11, p. 1213*).—A fungus which has been used against locusts at Cape Good Hope with good success was introduced into New South Wales and identified by the author as *Mucor racemosus*.

Locust destruction (*Agr. Jour. Cape Good Hope, 15 (1899), No. 7, pp. 480–483*).—Careful directions for the use of the locust fungus in combating these pests.

An insect powder duster for plants (*Sci. Amer., 81 (1899), No. 26, p. 404, figs. 4*).—A description of a blowgun provided with an apparatus for regulating the supply of powder to the discharge tube.

Rules and regulations of the Montana State Board of Horticulture (*Missoula: Montana State Bd. Hort., 1899, pp. 12*).—The act creating the board and prescribing its powers and the rules and regulations of the board, including the formulas prescribed for the treatment of insects and fungus diseases affecting nursery stock are given.

FOODS—ANIMAL PRODUCTION.

The relative digestibility of several sorts of fat by man. I, Margarin and natural butter, H. Lührig (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 6, pp. 481–506*).—The author reviews the literature of the subject and reports results of 4 experiments on the digestibility of margarin and butter made with a healthy man, 29 years old, weighing 74 kg. Holstein butter and 3 sorts of margarin were used, called, according to their quality, No. 1, 2, and 3. The tests were quite similar, the fat in each case forming part of a mixed diet of meat, bread, vegetables, etc. The composition of the margarin and butter was determined and the fat content of all the articles of diet. The average results of the tests follow:

Average digestibility of margarin and butter.

	Fat.		
	In daily food.	In daily feces.	Digested.
	Grams.	*Grams.*	*Per cent.*
Margarin No. 1, consumed with mixed diet 6 days	138.35	4.62	96.68
Margarin No. 2, consumed with mixed diet 4 days	118.64	3.91	96.70
Margarin No. 3, consumed with mixed diet 4 days	112.89	3.46	96.93
Butter, consumed with mixed diet 4 days	111.79	4.82	95.69

If corrections are made for the fat in the food supplied by other materials than margarin or butter, the average coefficients of digestibility in the 4 tests are 97.35, 97.39, 97.90, and 96.53 per cent, respectively. The author studied the undigested fat in the 4 experiments and determined the amount of true fat in the undigested ether extract. Taking account of these values, the corrected digestibility of the margarin and butter fat in the tests reported above is 98.31, 98.25, 98.46, and 97.77 per cent, respectively. In the author's opinion the true undigested fat was not butter or margarin fat, and accordingly he believes that it is safe to conclude that butter and margarin are completely digested. The fat recovered in the feces is believed to be derived from the digestive juices and metabolic products produced in the body during the experiment. If it is insisted upon that the 2 kinds of fat are not completely digested, it must still be granted that as regards digestibility they are practically alike, since the difference is very small.

The relative digestibility of several sorts of fat by man. II, Palmin, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 8, pp. 622–632*).—In continuation of previous work (see above) the author studied the digestibility of Palmin, a commercial preparation which is evidently a pure cocoanut butter. It is stated that this has a nutty odor and taste, and may be kept a long time without spoiling. Tests were made which showed that it was free from micro-organisms. The digestibility of this material was tested with the same subject as in the experiments referred to above. Two tests are reported. In the first 136 gm. of Palmin was taken daily for 3 days, and in the second, 90 gm. The Palmin formed part of a simple mixed diet of meat, bread, tropon, vegetables, etc. The average results of the tests follow:

Average digestibility of Palmin.

	Fat.		
	In daily food.	In daily feces.	Digested.
	Grams.	*Grams.*	*Per cent.*
First test, Palmin (cocoanut butter), consumed with simple mixed diet for 3 days	139.31	3.74	97.31
Second test, Palmin (cocoanut butter), consumed with simple mixed diet for 3 days	95.23	4.28	95.50

The results of these tests and a further study of the ether extract of feces leads the author to the conclusion that Palmin is as digestible as other sorts of fat used as food, and that this material, as well as butter and margarin, may be said to be completely digested.

The relative digestibility by man of several sorts of fat. III, Butter and margarin, H. LÜHRIG (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 10, pp. 769–783*).—In continuation of the author's previous work (see above), 4 experiments are reported, each of 3 days duration. In the first, 121.67 gm. of margarin was consumed daily with a simple mixed diet. In the second and third, 122 and 143 gm., respectively, of butter was consumed; while in the fourth experiment, which served as a check, no fat was eaten except the very small amount contained in the bread, beans, etc., making up the diet. The average results of the experiments follow:

Digestibility of butter and margarin.

	Fat.		
	In daily food.	In daily feces.	Digested.
	Grams.	*Grams.*	*Per cent.*
Margarin eaten with simple mixed diet	111.62	3.63	96.75
Butter No. 1, eaten with simple mixed diet	107.53	3.37	96.86
Butter No. 2, eaten with simple mixed diet	125.29	3.55	97.16
Mixed diet without the addition of fat	2.64	2.37	90.47

From a study of the chemical characteristics of the undigested fat the author introduces certain corrections in the above values and concludes that 97.86 per cent of the butter was actually digested and 97.55 per cent of the margarin. From a physiological standpoint the 2 fats are thought to be completely digestible and of equal value.

On some comparative analyses of and digestion experiments with wheat and whole-meal breads, O. Rosenheim and P. Schidrowitz (*Analyst, 24 (1899), Sept., pp. 227-231*).—The authors report the composition of ordinary white bread, ordinary whole-wheat bread, and a patent whole-wheat bread. In addition to the usual statistics, the analyses include phosphoric acid, soluble matter, the different constituents of the carbohydrate group, acidity, and in 2 cases the loss of water in 15 days.

Artificial digestion experiments with the 3 sorts of bread were made. These include salivary digestion, gastric followed by pancreatic digestion, and pancreatic digestion. The principal conclusions follow:

> "Although we do not desire to draw any sweeping conclusions from the experiments, owing to their limited number and somewhat restricted character, we feel justified in saying that they tend to bear out the opinion now generally held in scientific circles as to the great superiority of white bread as far as digestibility pure and simple goes. It is usually believed that whole-meal bread contains considerably more nitrogen than the white article, but this was certainly not the case in the breads examined by us; and although they were selected with care, there is sufficient variation in ordinary flours to account for this apparent anomaly. The whole-meal breads certainly contained considerably more ash, phosphoric acid, and soluble matter. The results obtained with the patent brown bread, in which the grain and husk are very finely comminuted, supports the contention that the digestibility and wholesomeness of whole-meal bread can be greatly improved by careful and thorough grinding and disintegration of the cellulose."

The estimation of cellulose in feces, K. Mann (*Arch. Hyg., 36 (1899), No. 2, pp. 158-165*).—The author reports experiments in which he himself was the subject. In the first period the food consisted of wheat bread, cheese, sausage, butter, and sugar. The total cellulose consumed per day was 1.1774 gm. In the second period the sausage and cheese were replaced by 72 gm. of elastin. When the cellulose in the feces was estimated by the Weende method, more was recovered than was consumed. The so-called cellulose was found to contain nitrogen and the material was studied at some length. The author concludes that in the presence of certain nitrogenous materials it is not possible to determine accurately the cellulose in feces by the Weende method. Elastin and other nitrogenous materials are not completely removed and in part account for the high values obtained. In addition to true proteids there are other materials containing less nitrogen and also nitrogen-free substances which are not removed from the feces by the Weende method. Assuming that the nitrogen found was all nitrogen of protein and that the remainder of the material consisted of cellulose, half the cellulose of fine wheat bread was found in the author's experiments to be dissolved in the intestinal tract.

Composition of lucern as affected by maturity, R. HARCOURT (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 23-29*).—This investigation includes a study of the yield, composition, and digestibility of different crops and cuttings of alfalfa. The total dry matter and the percentage composition of different crops and cuttings are shown in the following table:

Composition of different crops and cuttings of alfalfa.

	Total dry matter.	Protein.	Crude fiber.
Second crop, 1897:	*Pounds.*	*Per cent.*	*Per cent.*
First cutting	3,197	20.12	28.47
Second cutting	3,819	15.54	31.57
Third cutting	3,318	13.79	40.46
First crop, 1898			
First cutting	3,045	20.45	29.98
Second cutting	4,251	14.72	33.16
Third cutting	3,894	13.59	36.75
Second crop, 1898			
First cutting	1,899	16.77	26.10
Second cutting	2,505	16.32	31.46
Third cutting	2,214	14.30	35.81

The digestion experiments were made with sheep, with the following results:

Average digestibility by sheep of different crops and cuttings of alfalfa.

	Dry matter.	Protein.	Fat.	Nitrogen-free extract.	Crude fiber.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
First cutting	58.6	73.4	48.8	71.8	39.1
Second cutting	56.2	72.8	50.4	70.1	37.7
Third cutting	51.3	64.4	44.1	64.0	37.1

The author compares alfalfa with red clover and timothy hay. From the different tests the following conclusions were drawn:

> "Alfalfa deteriorates very rapidly both in percentage composition and in digestibility after the early blossoming stage. In our experimental work a much larger amount of digestible matter was obtained by cutting when the plants were about

one-third in blossom than by cutting either 2 weeks earlier or 2 weeks later. Alfalfa, cut when about one-third in bloom, compares very favorably in nutritive value with red clover and timothy. There appears to be danger in feeding alfalfa hay that has been made from the plant in advanced stages of maturity.

"Notwithstanding the rapidity with which alfalfa deteriorates after passing the early blossoming stage, the fact that when properly saved it yields a large amount of nutritious food makes it a most desirable addition to our list of fodders. In this report of the work done on alfalfa, no attempt has been made to treat of its value as a pasture crop or as a green fodder crop. Complaint has been made that cattle pastured on it show a tendency to bloat. Information is being gathered on this and other points, and a bulletin will be issued at an early date dealing with the whole question of alfalfa."

Alfalfa, or lucern, L. FOSTER and L. A. MERRILL (*Utah Sta. Bul. 61, pp. 155–214*).—The comparative yield, composition, digestibility, and feeding value of different crops and cuttings of alfalfa are reported upon. Tables are given which show the composition of different crops and cuttings of alfalfa from 1896 to 1898, and considerable material of this subject is quoted from a previous publication (E. S. R., 10, p. 977). The authors summarize the deductions regarding the composition of different crops and cuttings and similar topics as follows:

"The largest annual yield of hay per acre is obtained by the method of early cutting and the lowest by the late, the average result standing as follows: Early cutting 100, medium 92, and late 85.

"The early cut alfalfa contains the highest percentage of protein and fat, the most valuable food constituents, and the lowest percentage of crude fiber, the most indigestible portion. The former decrease constantly while the latter increases rapidly from early bloom to the full maturity of the plant.

"The proportionate amount of leaves to stems is greater at early bloom than at any subsequent time and both leaves and stems contain a greater percentage of protein and a less percentage of crude fiber at this time than at any later period in the growth of the plant. The relative proportion of leaves to stems in the different cuttings is as follows: Early 42 to 58, medium 40 to 60, late 33 to 67. . . .

"The first crop gave the largest yield in each of the 5 tests and in 14 out of the 15 cuttings, while the third crop gave the lowest for every test and in every cutting but one. . . .

"In the average composition of all cuttings for 3 years, the nutrients of the 3 crops vary but little. The second has slightly the highest percentage of protein and fiber; and the third the most fat and nitrogen-free extract.

"The third crop has the largest proportion of leaves to stems; but the percentage of protein in the leaves is highest in the second crop, and next highest in the first. The leaves of the first crop contain the most fat and of the second the least."

Feeding experiments (pp. 175–214).—Two feeding tests with steers are reported on the value of alfalfa of different crops and cuttings and comparing alfalfa with timothy hay, shredded corn fodder, red clover, and a mixture of alfalfa and straw. In each experiment these coarse fodders were each fed continuously to one lot of steers. The first test was made during the winter of 1897–98 with 36 two-year old steers divided into 12 lots of 3 each. It lasted 111 days, during a part of which time grain was fed with the coarse fodder.

The second test was made during the winter of 1898–99 with 27 two-year-old steers. The experiment lasted 112 days, grain being fed with the coarse fodder the entire time.

The results are tabulated for each experiment and are discussed at some detail, together with the results of 5 years' experiments at the station. The following is a summary of the deductions drawn from the 2 present experiments:

> "In the feeding tests, the highest gains were made from the early cuttings and the lowest from the late, the results standing proportionately as follows: Early cutting, 100; medium, 85; and late, 75.
>
> "The variation in the amount of the different cuttings eaten per day was very slight, being the highest for the early cutting and the lowest for the late, but the quantity of dry matter and also of digestible matter required for a pound of gain was decidedly lowest for the early cutting and highest for the late, the relative amounts of dry matter standing as follows: Early cutting, 100; medium, 131; and late, 66.
>
> "The annual beef product per acre was largest from the early cuttings, not only in the general average but in each separate season's test, and that from the late cuttings was smallest, the proportional products standing as follows: Early cutting, 100; medium, 79½; and late, 69½.
>
> "Taking all points of comparison into consideration, both separately and collectively, including everything that pertains to the largest yield and highest feeding value, the tests favor cutting alfalfa for cattle feeding when the first blooms appear . . .
>
> "The beef product per acre, taking the average result of all cuttings for the 5 years, was very much the highest for the first crop and decidedly the lowest for the third, standing as follows: First crop, 100; second, 61; and third, 45; but taking the early cuttings alone they stand, first crop, 100; second, 80; and third, 69.
>
> "Pound per pound, taken as a whole, the results show the highest feeding value for the third crop and the lowest for the second.
>
> "The average annual beef product from early cut alfalfa was 705.61 lbs. per acre; it required 9,575 lbs. of timothy to produce an equal weight; 11,967 lbs. of red clover and 10,083 lbs. of shredded corn fodder."

In calculating the financial results the following prices were used: Alfalfa $4, shredded corn fodder $5, timothy hay $6, bran and shorts $10, chopped wheat $16, and chopped corn $16 per ton. On this basis there was a loss in both cases.

> "If the steers of the first test could have been disposed of at the close of the experiment, the loss would have been very much less. The gains from the after feeding were equal in value to only a little more than half the cost of the food that produced them. The increased grain ration added largely to the expense of feeding during this latter period. Judging from the results of the 2 tests here reported, the margin between the purchase and selling prices has been too small for the past 2 years to warrant feeding with foods, especially grains, at as high prices as those used in estimates herein reported."

Experiments in cattle feeding, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 75–80*).—Two tests on fattening steers are reported.

Different quantities of meal for fattening steers (pp. 75–77).—Nine steers were divided into 3 lots of 3 each. Lot 1 was fed a medium grain ration, consisting of equal parts of ground peas, barley, and oats, the amount fed being increased rapidly until the ration reached, as nearly as possible, 1 lb. of meal per 100 lbs. of live weight. Lot 2 was fed the same ration, the amount fed being increased until ⅔ lb. of grain per 100 lbs. of live weight was fed. At the beginning of the trial lot 3 received ½ lb. of the same grain ration per 100 lbs. of live weight. This amount was increased as seemed advisable until the amount fed was the same as that given lot 2. In addition to the grain, all the steers were fed a mixture of hay and straw during the first part of the trial (later on hay alone), together with 15 lbs. of roots per day. The quantity of roots was later increased to 25 lbs.

The test proper began December 3 and covered 179 days. It was preceded by a preliminary period of 30 days under the same conditions. Before the close of the test, 1 steer in lot 2 and 1 in lot 3 were dropped. The total weight of the 3 steers in lot 1 at the beginning of the test was 3,235 lbs.; of the 2 steers in lot 2, 2,245 lbs.; and of the 2 steers in lot 3, 2,241 lbs. The average gain per steer was 301.66 lbs., 285 lbs., and 297 lbs., respectively. The average amount of meal consumed per day per pound of live weight was 0.81 lb., 0.65 lb, and 0.53 lb., respectively.

The financial statement is based on meal at $13, hay $6, straw $3, and roots $2 per ton. The average cost of a pound of gain was for lot 1, 7.7 cts.; for lot 2, 7.26 cts.; and for lot 3, 6.46 cts.

This test is a duplicate of a previous one (E. S. R., 10, p. 277), and the results of the two are compared:

> "In the case of the light and medium rations, the results of the 2 experiments are somewhat contradictory, since in the first experiment the medium ration proved to be the more economical of the two, while in the second experiment this result has been reversed. But in both experiments the results have been decidedly in favor of the 2 lighter rations as compared with the heavy ration. The results of the 2 experiments, therefore, point to the conclusion that for fattening steers a moderately light meal ration is more profitable than a heavy meal ration, provided, of course, that the coarser fodders are of good quality and palatable."

Corn vs. peas for fattening steers (pp. 77, 78).—The relative value of corn and peas was tested with 2 lots of 3 steers each. Lot 1 was fed a grain ration consisting of equal parts of ground corn, barley, and oats, and lot 2 a ration of equal parts of peas, barley, and oats. The amounts of grain, hay, and roots fed were the same as in lot 2 in the preceding test.

The financial statement is based on meal at $13, hay $6, straw $3, and roots $2 per ton. Lot 1 weighed 3,233 lbs. at the beginning of the trial, December 3. During the 179 days of the test, the average daily gain per steer was 1.75 lbs., and the cost per pound of gain, 6.56 cts. Lot 2 weighed 2,245 lbs. at the beginning of the trial. The average gain per steer was 1.59 lbs., and the cost of a pound of gain, 7.26 cts.

"In this experiment, therefore, corn, barley, and oats gave much better results than peas, barley, and oats." The author believes that the gains are influenced greatly by the individuality of the steers and that the comparison is not altogether satisfactory. "Though the results are decidedly in favor of corn as compared with peas for fattening steers, the experiment will be repeated."

Pasteurized vs. raw skim milk for calves, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, p. 66*).—A test with 4 calves comparing pasteurized and raw skim milk is briefly reported. After a preliminary period of 1 week, the test proper began July 18, 1898, and covered 2 periods of 4 weeks each. The periods were separated by an interval of 1 week. In the first period calves Nos. 1 and 2 were fed pasteurized skim milk and Nos. 3 and 4, raw skim milk. In the second period the conditions were reversed. "In addition to the milk and meal, all the calves were fed some hay and green feed; the amount varied according to appetite." The weights of the calves at the beginning of the test were 536, 352, 298, and 228 lbs., respectively, and the corresponding gains during the whole period were 139, 163, 128, and 134 lbs., respectively.

> "All the calves appeared to thrive equally well whether fed on the pasteurized or on the raw skim milk. . . . It would seem that after calves receive a fair start they will do well on skim milk, meal, green feed, and hay. The gains were good and in this experiment 3 of the 4 calves made the greatest gain on the pasteurized skim milk along with meal and other food. To prevent skim milk souring at the creamery or on the farm, pasteurization is the most practicable method; and all creameries should adopt this plan, in order to return the skim milk in good condition to the farm, and thus preserve valuable food for calves and pigs."

Experiments in sheep feeding, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 81, 82*).—Two tests with sheep are briefly reported. In the first a comparison of alfalfa and red-clover hay for lambs was made. Thirteen lambs were divided into 3 lots; lots 1 and 3 contained 4 lambs each and lot 2, 5. The test covered 74 days. Lot 1 was fed red clover hay, lot 2 first crop alfalfa hay, and lot 3 third crop alfalfa hay. In addition all the lots were fed equal amounts of corn and peas 1:1. The red clover and first crop alfalfa hay had been injured by rain; the third crop alfalfa hay was "in very good condition and was much finer in stock than the first crop."

The financial statement is based on oats at 25 cts. and peas at 48 cts. per bushel and hay at $6 per ton. The lambs in lot 1 made an average weekly gain of 2.1 lbs., consuming 5.14 lbs. of meal and 9.03 lbs. of hay per pound of gain. The cost of a pound of gain was 6.63 cts. The average weekly gain made by the lambs in lot 2 was 2.15 lbs. The meal and hay consumed per pound of gain was 4.93 and 8.43 lbs., respectively; the cost of a pound of gain was 6.32 cts. The lambs in lot 3 made an average weekly gain of 2.31 lbs. and consumed 4.67 lbs. of meal and 8.2 lbs. of grain per pound of gain, the cost of a pound of gain being 6.05 cts.

The principal conclusions follow: "In all groups there was some hay wasted, the waste in the case of the first crop alfalfa being considerably greater than in the other two. . . . So far as the experiment goes it would indicate that the feeding value of alfalfa hay approaches very closely to that of red clover when fed to sheep."

In the second test, which also covered 74 days, corn and peas as a fattening ration were compared on 2 lots of 4 lambs each. Lot 1 was fed peas and oats 1:1 and lot 2 corn and oats 1:1, both lots being given clover hay in addition.

The financial statement is based on peas at 48 cts. and corn at 38 cts. per bushel and hay at $6 per ton. The values for corn and peas include the cost of grinding. The results of the test are shown in the following table:

Results of feeding corn and peas to lambs.

	Meal consumed.	Hay fed.	Average weekly gain.	Meal consumed per pound of gain.	Hay fed per pound of gain.	Cost of food per pound of gain.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*	*Pounds.*	*Cents.*
Lot 1 (peas and oats)	456.75	802	2.10	5.11	9.03	6.63
Lot 2 (corn and oats)	456.75	802	2.29	4.72	8.27	5.79

"This experiment gives a marked difference in favor of the corn, both in rate of gain and cost of gain, and at the same price per pound for corn and peas the corn would still have the advantage. Further tests are necessary and preparations are being made for repeating the experiment."

Roots as food for pigs, C. S. PLUMB and H. E. VAN NORMAN (*Indiana Sta. Bul. 79, pp. 53-62*).—In 1898 as high as 24.25 tons of mangel-wurzels per acre were produced at the station at a cost of 85 cts. per ton when harvested. Their feeding value was tested with 12 pigs, 7 of which were pure bred Chester Whites and the remainder Chester White-Poland Chinas. The pigs were weaned only 2 days before the beginning of the test, when they were about 3 months old. They were divided into two uniform lots, each lot containing 3 males and 3 females. The test began February 1 and closed April 19, 1899. The pigs were confined in small lots 15 by 30 ft. in size, with a comfortable shelter house in each lot. Lot 1 was fed a slop consisting of corn meal and shorts, 1:2, and cut mangel-wurzels *ad libitum*, Lot 2 was fed corn meal and shorts only. The pigs were supplied with water, ashes, and salt. Weighings were made at the end of each week. At the beginning of the test the average weight of the pigs in the 2 lots was 44 and 46.1 lbs., respectively. The average daily gains in the 2 lots were 4.61 and 5.74 lbs., respectively. Each lot consumed 3.71 lbs. of meal and shorts per pound of gain. In addition to the grain ration, lot 1 ate 514 lbs. of mangel-wurzels during the test. Rating the corn meal at 80 cts., shorts at 70, and mangel-wurzels at 10 cts. per hundred pounds, the cost of food per pound of gain was 2.8 and 2.7 cts., respectively. The authors compute the amount of digestible nutrients in the rations eaten.

"The mangels were fed only as eaten up clean, and the pigs did not eat them with the relish that might have been anticipated. The cut roots were mixed with the grain slop, and the pigs would clean up the slop in preference to the roots as a general rule, eating the latter quite leisurely. . . . It required exactly the same amount of corn meal and shorts to make a pound of gain with each lot. . . . The total cost of all food for each pound of gain for lot 1 was slightly in excess of the cost for lot 2, the roots making this extra expense, which amounted to 10 cts. for each 100 lbs. of gain in live weight."

The authors continued the experiment from April 19 to June 7 in order to determine whether a succulent ration had any beneficial aftereffects, each lot being fed a ration of corn meal and shorts. The average weight of the pigs in lot 1 at the beginning of this test was 113.3 lbs., and of those in lot 2, 129.1 lbs.; the average daily gains were 8.39 and 8.55 lbs., respectively. The pigs in lot 1 required 4.44 lbs. of grain valued at 2.99 cts. to make a pound of gain; those in lot 2, 4.36 lbs. valued at 2.98 cts.

"If the mangels were of value in the feeding, the figures show it in only a small way. The mangel-fed pigs were no more healthy at any time . . . than were those not so fed, while it has been shown that the cost of producing flesh with them was slightly more than with the others. The difference, however, was so slight, that a redistribution of the pigs, or a substitution of another in lot 1 might have reversed the results. . . .

"The writers feel that roots in some form are a desirable food for pigs in winter, as an addition to the grain ration, in promoting healthy activity of the digestive organs and acting as an appetizer. Sugar beets, artichokes, or carrots would no doubt serve this purpose better than mangels They are more expensive in view of greater cost of production, but this difference is not important. They, however, contain enough more sugar to make them somewhat better relished by the pigs than are the mangels."

Experiments in swine feeding, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 82–91*).—Several experiments with different feeding stuffs and with breeds of pigs are reported.

Experiments with pure-bred swine (pp. 82–86).—This is in continuation of previous work (E. S. R., 10, p. 278.) Thirty-six pigs were divided into 3 lots of 12 each, containing 2 pigs of the following breeds: Yorkshire, Chester White, Tamworth, Duroc Jersey, Poland China, and Berkshire. The pigs were from 7 to 9 weeks old when purchased. From June 14 until the beginning of the experiment proper, July 4, they were fed under conditions similar to those in the experiment proper to accustom them to their changed surroundings and feed. The test covered 112 days. Lots 1 and 2 were confined in pens, the pigs of each breed being kept separate. Each pen opened into a small yard. Lot 3 was given the run of a half-acre lot with shelter. For about a month the pasture furnished some grass and clover. All the pigs were fed the same grain ration. Until August 19 this consisted of wheat middlings; from August 19 until September 12 of equal parts of barley and shorts; and from September 12 until the close of the experiment of equal parts of peas, barley, and shorts. In addition, whey was fed lot 2. In discussing the gains made by the different breeds, lots 1 and 2 were compared. The results are summarized in the following table, the breeds being arranged in the order of economy of gain. No account was taken of the whey, since the amount fed was the same for all breeds.

Results of feeding pure-bred swine.

Breed.	Average weight at beginning of test.	Total gain per pig in 112 days.	Average daily gain per pig.	Meal consumed per pound of gain.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*
1, **Yorkshire**	52.00	123.75	1.10	3.50
2, **Berkshire**	49.50	120.00	1.07	3.70
3, Duroc Jersey	59.25	120.00	1.07	3.76
4, Tamworth	47.75	119.25	1.06	3.78
4, Chester White	56.00	119.25	1.06	3.78
5, Poland China	68.75	117.75	1.05	3.83

"The uniformity of the gains of the different breeds is rather remarkable. The Yorkshires and Berkshires consumed rather less meal than the other breeds, and this accounts for the considerable difference in the quantities of meal required for 100 lbs. of gain. The Poland Chinas were placed at a slight disadvantage, in that they were heavier than the other breeds "

At the close of the test the pigs were sold and slaughtered, the carcasses being judged by an expert with a view to their value for bacon.

"On the whole the breeds rank pretty much the same as in previous years. It is worthy of note that it did not cost more in this feeding test to produce a pound of gain in the case of a good type of bacon hog than in the case of less suitable types.

"The experiment also indicates that while the bacon type is apparently more common in some breeds than others, yet very good bacon types occur in practically all the breeds tested. The selection of breeding stock, however, to conform to the bacon type, among some of the breeds tested, would mean a divergence from the standards of excellence provided for the direction of breeders."

The feeding value of whey, the influence of exercise on growth, and the amount of meal required per pound of gain at different weights are discussed with the 3 lots.

"In this experiment 100 lbs. of whey proved equal in feeding value to 14 lbs. of meal, showing that whey is valuable food for swine when fed judiciously . . . There is a steady increase in the amount of meal required to produce a pound of gain as the hogs increase in weight, and [this] is a strong argument in favor of marketing hogs by the time or a little before they reach 200 lbs. live weight."

Rape for fattening hogs (pp. 86–91).—Two tests were made of the value of rape for fattening pigs. Further, corn meal was compared with peas, barley, and shorts, 1:1:1, with the same lots with special reference to the effect of these feeding stuffs upon the firmness of bacon. The first test, which covered 42 days, was made with 3 lots of 4 pigs each. Lots 1 and 2 were fed corn meal, lot 1 receiving only two-thirds as much as lot 2. Lot 3 was fed a mixture of equal parts by weight of peas, barley, and shorts. In addition to the grain ration, lot 1 was fed all the rape they would eat up clean. The results of the tests follow:

Results of pig-feeding tests.

	Average weight of pigs at beginning of experiment.	Total gain per pig.	Average daily gain per pig.	Food consumed per pound of gain.	
				Grain.	Rape.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*	*Pounds.*
Lot 1 (corn and rape)	118	61	1.45	2.61	8.48
Lot 2 (corn alone)	107	64	1.52	3.69	....
Lot 3 (peas, barley, and shorts alone)	104	60	1.42	3.93	....

The second test also covered 42 days, and was made with 2 lots of 4 and 1 of 3 pigs. Lots 1 and 3 were fed a mixture of equal parts by weight of peas, barley, and shorts; lot 2 was fed corn meal. The amount of grain fed lot 1 was two-thirds of the amount fed lot 2, but in addition to the grain lot 1 was fed rape. The results of the test follow:

Results of pig-feeding tests.

	Average weight of pigs at beginning of experiment.	Total gain per pig.	Average daily gain per pig.	Food consumed per pound of gain.	
				Grain.	Rape.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*	*Pounds.*
Lot 1 (peas, barley, and shorts with rape)	100	47	1.12	2.79	8.47
Lot 2 (corn alone)	94	46.5	1.10	4.09	
Lot 3 (peas, barley, and shorts alone)	107	51	1.21	3.88	

In the author's opinion, the 2 tests show no great variation due to the different feeding stuffs.

"The most striking feature of the experiment is the marked saving in meal required for 100 lbs. of gain effected by the use of rape. It indicates that rape has a very considerable value as a food for hogs; but, owing to the somewhat contradictory results in connection with its effect on the firmness of bacon, it is hardly safe to recommend it for hog feeding until it has been further tested."

On the basis of all the tests reported, the influence of feeding and exercise on the firmness of bacon is discussed. The conclusions are summarized as follows:

"Corn apparently produces no evil effects upon the firmness of bacon when used for finishing hogs that have plenty of exercise until they reach about 100 lbs. live weight. Neither does corn appear to have any bad effects when used for finishing hogs that have had no exercise, but have been fed skim milk with a mixed grain ration until they reach 100 lbs. live weight.

"What has been said of corn may also apply to rape, when fed with a two-thirds meal ration, though the evidence is somewhat conflicting on this point.

"Hogs confined in pens and fed on wheat middlings during the early stages of growth, and on peas, barley, and shorts during the finishing period, have a marked tendency to softness. Hogs given plenty of exercise, and fed as just described, produce firmer bacon than those confined in pens. The evil effects arising from lack of exercise can be overcome by the judicious use of skim milk and whey. The amount of whey recommended is from 2 to 2½ lbs. of whey to 1 lb. of meal. Whey and skim milk appear to have a greater influence than exercise in producing firm bacon. Unthrifty hogs are more likely to produce soft bacon than growthy, well-fed hogs.

"The points mentioned above are not offered as definite conclusions, for the investigation is only well begun. On the whole, however, there seems to be nothing in the results which might not reasonably be expected—a fact which adds to their value in no slight degree."

Report of manager of poultry department, L. G. Jarvis (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 193–196*).—The work of the poultry department is briefly reported.

Egg preservation (pp. 193, 194).—In tests with a solution of lime and water glass (sodium silicate) for preserving eggs the best results were obtained with water glass. Satisfactory results were obtained when a solution of 1 part of water glass to 15 parts of water was used, and with 1 part of water glass to 20 parts of water.

Feeding ducks for market (pp. 194, 195).—Seven Pekin and 9 Rouen ducks were fed from the time they were hatched until 10 weeks old. The first 2 weeks they were given a ration consisting of equal parts of corn meal, wheat bran, and middlings mixed to a thick mush with hot water. They were fed 5 times a day all they would eat up clean. During the remainder of the test the ration consisted of wheat bran and middlings, 2:5. This was also fed in the form of a mush. All the ducks were given grit and sharp sand. No water, except for drinking purposes, was supplied them.

When 6 weeks old, the 7 Pekin ducks weighed 39 lbs., and the 9 Rouen ducks, 36 lbs. At the close of the test, or when 10 weeks old, the Pekin ducks weighed 59½ lbs., and the Rouen ducks, 63 lbs.

"By selecting the right varieties of ducks, and feeding them on the right kinds of food, you can get them on the market when 6 weeks old. We also find that water is not needed, except for drinking purposes, but is a hindrance to the growth and fattening of ducks.

"We selected two of the best varieties of ducks for market purposes; and while they have the same standard weight, when fully matured, the experiment plainly shows that the Pekins can be made to take on flesh faster than the Rouens. No ducks should be kept longer than 10 weeks, as they can be placed on the market at that age and sold at a good profit.

"Ducks that are intended for breeding purposes should not be fed on a fattening ration, so as to weaken them by too much forcing. They should be selected when about 6 or 7 weeks old, when their sex can readily be seen and the most perfect specimen selected."

Tests on fertility and egg production (pp. 195,196).—Several tests were made on the production and fertility of eggs. Ten laying hens were separated from the male. The eggs laid each day were placed in an incubator and their fertility tested. Of the eggs laid during the first 4 days after the male was removed 70 per cent were fertile; of those laid on the fifth day, 61 per cent; on the sixth, 60 per cent; on the seventh, 49 per cent; on the eighth, 12 per cent; on the ninth, 2 per cent; and on the tenth, all were infertile.

A test was also made with 6 laying hens to determine the time which must elapse before eggs become fertile after a male is introduced. On the third day, 30 per cent of the eggs were found to be fertile; on the fourth, 42 per cent; on the fifth, 50 per cent; on the sixth, 60 per cent; on the seventh, 70 per cent; on the eighth, 68 per cent; on the ninth, 70 per cent; on the tenth, 74 per cent.

The influence of the male on the total number of eggs produced was also tested with 2 lots. Lot 1 consisted of 5 pullets, 5 hens, and 1 cock; lot 2, of 5 hens and 5 pullets of the same varieties as lot 1. The test began January 1 and lasted until September 1. Both pens were fed and cared for in the same way. Lot 1 laid 959 eggs and lot 2, 972 eggs. "It can be seen that there was but very little difference in the number of eggs laid by the 2 pens."

Brief statements are also made concerning the different cross breeds of chickens raised at the station.

Dietetic preparations of recent origin, H. Bremer and L. Geret (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 10, pp. 791-793*).—A summary is given of this paper which was presented at the 71st meeting of the German Naturalists and Physicians at Munich, September, 1899.

Concerning meat extract, H. Bremer (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 10, pp. 793, 794*).—A summary of a paper presented at the 71st meeting of the German Naturalists and Physicians at Munich, September, 1899.

The nutritive value of beef prepared in the ordinary ways, G. Lebbin (*Aerztl. Sachverständ. Ztg., 4 (1898), pp. 437-440; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 7, pp. 575, 576*).—This article is evidently a résumé of an investigation by K. Förster, previously noted (E. S. R., 10, p. 662).

The comparative dietetic value of wheat and whole wheat bread (*Lancet [London], 1899, No. 3971, p. 852*).—A brief general discussion.

Cotton-seed oil as food (*Lancet [London], 1899, No. 3961, pp. 294, 295*).—A brief note on the subject.

A contribution to the study of caseon, M. Wintgen (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 10, pp. 761-769*).—The composition, properties, and digestibility of caseon, a proteid preparation made from skim milk, are reported upon. The digestion experiments were made with 2 men, caseon being eaten with rice, wheat bread, butter, and sugar.

Condensed milk, T Macfarlane and A. McGill (*Lab. Inland Rev. Dept. Ottawa, Canada, Bul. 51, pp. 28*).—The authors report the analysis of 66 samples of condensed milk. The bulletin also contains a section on analytical methods.

Report of the analyst, A. E. Leach (*Massachusetts State Bd. Health Rpt. 1898, pp. 695-719*).—In addition to statutes regarding the purity of foods, drugs, etc., examined, the composition of a number of samples of condensed milk is reported.

Infants' and invalids' foods, T. Macfarlane and A. McGill (*Lab. Inland Rev. Dept. Ottawa, Canada, Bul. 59, pp. 24*).—Analyses of a large number of samples of commercial foods for infants, children, and invalids are reported. The analytical methods followed are described. The different classes of these foods and their food value are discussed.

Contribution to the study of ropy bread, A. Juckenack (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 10, pp. 786-788*).—A summary of a paper presented at the 71st meeting of the German Naturalists and Physicians at Munich, September, 1899.

The behavior of elastin in the metabolism of man, K. Mann (*Arch. Hyg., 36 (1899), No. 2, pp. 166-177*).—Experiments on the value of elastin in which the balance of income and outgo of nitrogen was determined are reported. The author was himself the subject.

How far is alcohol a protector of protein, T. R. Offer (*Chem. Ztg., 23 (1899), No. 79, p. 833*).—A brief note of the author's paper presented before the Section of Physiology at the September meeting of the Society of German Naturalists and Physicians in Munich. Basing his deductions on metabolism experiments in which he was himself the subject, the author concludes that alcohol actually protects protein, though its value for this purpose is not great.

The examination of food preparations, C. Posner (*Berlin. Klin. Wchnschr., 35 (1898), pp. 654-661*).

The identification of the chaff occurring in foods and feeding stuffs, J. Formánek (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 11, pp. 833-842, figs. 9*).

On the occurrence of phytosterin in the animal body after ingestion of cotton-seed meal, C. Virchow (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 7, pp. 559-575*).—A number of experiments with dogs and pigs are reported. According to the author his investigations substantiate A. Bömer's conclusion that phytosterin can not be taken up into the fatty tissue of animals.

Live stock, W. Rennie (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 188-192*).—Statistics are given of the steers, milch cows, sheep, pigs, and horses kept at the farm. The steers were fed a mixed ration consisting of chopped grain and bran with cut corn fodder, chaff, pulped roots, silage, turnips, etc. The rations were varied somewhat each month and at no one time were all the materials fed.

Fifteen steers at the beginning of the trial weighed 13,333 lbs., and in 6 months made an average monthly gain of 291$\frac{7}{15}$ lbs.

Horse breeding, M. Fischer (*Fühling's Landw. Ztg., 48 (1899), No. 21, pp. 798–809, figs. 5*).—A general article.

The economic feeding of working horses, T. U. Walton (*Rpt. Australian Assoc. Adv. Sci. 1898, pp. 953–955*).—Abstracted from another publication (E. S. R., 11, p. 74).

Geese and geese breeding, E. Brown (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 2, pp. 313–351*).—The author discusses at length the uses, varieties, feeding, and killing and dressing of geese and the geese-breeding industry. Numerous references to the literature of the subject are made.

DAIRY FARMING—DAIRYING.

Testing cows at the farm, E. H. Farrington (*Wisconsin Sta. Bul. 75, pp. 30, pls. 8, fig. 1*).—A detailed account is given of farm tests extending through 1 year of 6 dairy herds supplying milk to the university creamery.

The milk of each cow was weighed and sampled by the patron at the morning and night's milking one day in each week, and the samples were tested at the creamery. The mixed milk from each farm was also weighed and tested when received at the creamery, and a comparison made of the farm and creamery weights and tests, to determine the accuracy of the farm records. "The results show that tests of dairy cows can be made by the farmers themselves with sufficient accuracy to give a very satisfactory knowledge of the performance of each cow."

The complete details of the weekly tests of one cow are given to illustrate the method employed in calculating the total milk and fat production. Notes are given on the feeding of the cows at the different farms, which was according to the usual practice of the owner. The cost of feed for one herd of 12 cows, as estimated by the owner, was $355, and the receipts from the milk at the creamery, calves, and skim milk amounted to $698, making an excess of receipts above cost of feed of $28 per cow. Tables show the annual production and creamery value of the milk of each of 33 cows, representing 4 herds, tested through one period of lactation.

The extreme variation in the butter value of the cows on 4 of the farms is shown in the following table:

Range in value of annual products.

	Farm A.	Farm B.	Farm C.	Farm D.
Best cow	$53.35	$58.20	$60.72	$55.49
Poorest cow	$28.72	$44.83	$37.96	$39.60
Average cow	$36.30	$50.00	$48.83	$44.12
Number of cows in the herd	12	5	12	4

The differences in profit from the poorest and the best cows are pointed out. Illustrations from photographs are given of 14 different cows, which were in the above tests, together with their records.

In discussing the most profitable month for fresh cows a table is given showing the average prices received per pound of fat for the total production of cows fresh in the different months, from which it appears that the highest price was received for cows fresh in September and the lowest for cows fresh in December.

Semimonthly tests of one day each are considered satisfactory in determining the total production of a cow. In this connection work published by the author in Bulletin 24 of the Illinois Station (E. S. R., 4, p. 944) is summarized.

Milking cows twice and three times per day, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, p. 65*).—Two cows were milked 3 times per day for 2 weeks, and after an intervening period of 1 week, were milked twice per day for 2 weeks. The rations were changed during the intervening period. A table shows the amounts of food consumed and the milk and butter produced. When milked twice per day, one cow gave 13 lbs. of milk less and 0.39 lb. of fat more, and the other cow 5 lbs. of milk and 1.35 lbs. of fat less in the 2 weeks than when milked 3 times per day.

"In the case of these 2 cows, one of which produced an average of 52 lbs. of milk per day, and the other about 12 lbs. per day, it did not pay to milk them 3 times a day. With cows producing 60 lbs. of milk or over per day it will likely be profitable to milk them 3 times a day."

On the formation of fat in the animal organism by intensive feeding of fat, V. HENRIQUES and C. HANSEN (*41 Ber. K. Vet. Landbohöjskoles Lab. Landökon. Forsög* [*Copenhagen*], *1899, pp. 40, col. charts 3*).—The author studied the question of the formation of fat in the body of pigs and in the milk glands of cows by heavy feeding of fat.

Experiments with pigs.—In the experiments with pigs, 2 three-months-old pigs were fed for a period of 168 days on rations consisting of ground barley and varying amounts of cocoanut oil or linseed oil. The oil was mixed with the ground barley (in case of cocoanut oil, after it had been melted), and the mixture made into a slop with water. The changes in the chemical composition of the body fat of the animals were studied by removing at different periods a portion (5 to 10 gm.) of the fatty tissue underlying the skin on the backs of the animals. A cocain solution was injected prior to the operation and the wound properly dressed afterwards. The fatty tissue was warmed to 100° C. in a current of carbon dioxid, pressed through a piece of muslin, and the liquid fat cleared by filtering through filter paper. The fat was examined for iodin number, index of refraction, and for drying oils.

The feed of the pigs during 5 periods of the experiment, in which the fat of the food was gradually increased, with results of the examinations of the body fat of each pig at 4 different dates and at slaughtering time, are given in the following table:

Feed given and results of fat examinations.

Period.	Feed per day.				Date of sampling.	Examination of body fat.			
	Pig 1.		Pig 2.			Pig 1.		Pig 2.	
	Oil.	Barley.	Oil.	Barley.		Iodin number	Refraction.	Iodin number	Refraction.
	Gm	*Gm.*	*Gm.*	*Gm.*					
Oct. 1-15	*a* 125	725	*b* 125	1, 000	Oct. 10	70. 3	60. 5	70. 9	60. 8

a Cocoanut oil. *b* Linseed oil

The data furnish proof of the presence of the linseed oil in the newly-formed fat of the body of the pigs. As the iodin number of pure olein is 86.2, there must have been found large quantities of glycerids of the linoleic acid series in the fat at the time of the heavy linseed oil feeding, the iodin number of linoleic and linolenic acids being 181.4 and 274, respectively, while that of the linseed oil fed was 177.2, and that of cocoanut oil 8.1. The oxy-acid of linoleic acid, sativic acid, was also found present in large quantities in the fatty tissue of the pigs obtained at slaughtering time.

Experiments with cows.—The experiments were suggested largely by Soxhlet's recent trials with feeding fat in emulsion to milch cows (E. S. R., 8, p. 1016). Two cows were fed a basal ration of hay and extracted linseed meal (containing 0.3 per cent of fat), to which linseed oil in varying quantities was added. Cow 1 received 12 kg. of hay, 0.75 kg. of linseed meal, and 0.5 kg. of linseed oil in emulsion per day. Cow 2 received 8 kg. of hay, 1.25 kg. of ground barley, 0.75 kg. of linseed meal, and amounts of linseed oil ranging from 0.5 to 1 kg. per day. When the quantity of oil was increased to 1 kg the cow lost her appetite and soon had tympanitis. The experiment lasted from June 6 to July 23 for cow 1, and from October 25 to April 12 for cow 2. The milk yield of the cows, and the composition of the milk and butter, were determined during the progress of the experiment, the iodin number, refraction, volatile acids, and melting point of the butter being ascertained.

The results obtained show that the percentage of fat in the cows' milk as a rule increased during the first 4 to 6 days of oil feeding, in single cases nearly 1 per cent; after 10 to 15 days, however, the fat content again became normal, in spite of the fact that the oil emulsion feeding was continued. The yield of milk and of fat changed with the oil feeding in the same manner as the percentage of fat in the milk.

The examinations of the butter fat showed that the volatile fatty acids decreased greatly during the linseed-oil feeding (lowest Reichert number obtained for cow 1 being 16.5 and for cow 2, 12.5, for 5 gm. of fat). This effect of the oil feeding was much more persistent than on either the yield or fat content of the milk, and on discontinuance of the oil feeding the return to a normal volatile acid content came but slowly. The iodin number rose and fell rapidly with the feeding of oil and discontinuance of it. The maximum number obtained was 70.4 (cow 2). As only small quantities of linoleic acid were found in the fat (see below), the increased iodin number must have been due to an increase in the olein content of the fat on oil feeding. The index of refraction changed in the same manner as the iodin number, the curves for the two sets of determinations following each other closely throughout the experiments. The increase due to the oil feeding was very marked and rapid, with the maximum appearing about the fifth day of the oil feeding. The melting point of the fat increased in the same manner as the iodin number, viz, from 35.4 (normal ration) to 39° C. (0.5 kg. linseed oil).

The amount of sativic acid in 50 gm. of butter fat (determined by Hazura's method) in the different periods was (for cow 2) as follows: Trace, 0.012, 0.013, and 0.037 gm. A mixture of butter fat containing 15 per cent of linseed oil gave by the same method 0.842 gm. of sativic acid.

A direct transfer of food fat to milk fat is therefore of small importance. Soxhlet's theory that the food fat is deposited in the body, and the body fat changed into milk fat is shown to be wrong by the results of the Hübl test, since the iodin number of beef fat is 40, while that of the butter fat on the oil feeding was about 58. By partially starving a milch cow the volatile acids in the fat were not appreciably changed, while a marked increase was found in the iodin number and a decrease in the melting point. It seems probable, therefore, in the opinion of the authors, that during inanition the fatty body tissue is deprived especially of the liquid compounds (olein), which pass over into the milk fat.

The general conclusion is drawn that when a large quantity of fat is supplied to the animal organism in the food it will, after having been transferred to the blood, be secreted as milk fat, but the secretion can not be looked upon as a direct transmission of the fat from the blood to the milk glands. The fat added will be worked over in passing through the alveoli cells of the milk gland in such a manner that a large amount of olein and a small amount of a fat having a high melting point (stearin?) are formed. If there are large quantities of drying oils in the fat consumed, these will be changed to nondrying oils before being secreted in the milk.—F. W. WOLL.

Effect of drought on the quality of milk, A. W. STOKES (*Dairy, 31 (1899), No. 130, pp. 292, 293*).—In the inspection of milk furnished by farmers to wholesale dealers in London a number of samples were found having over 13 per cent total solids and less than 8.5 per cent solids-not-fat. To determine the cause of these abnormal milks the author visited one of the farmers and took samples of the milk from his herd of 35 cows. Three samples were from individual cows and 10 were composite samples representing 2 to 5 cows each. Of the 13 samples only 2 were above 8.5 per cent solids not fat. The mixed milk of the herd contained 12.6 per cent total solids and 7.85 per cent solids not fat. The production of this abnormal milk is considered as influenced by the prolonged heat of the summer, the extra work involved in securing sufficient food from the dried-up pastures, and the unlimited water supply accessible to the cows.

Of 3,641 samples analyzed during July, August, and September, 1898, 196 were found to contain over 12 per cent total solids and less than 8.5 per cent solids not-fat. Similar results were obtained during the corresponding months in 1899. During prolonged dry seasons the author urges caution in condemning milk as watered which has 12 per cent total solids.

The pathology of milk, G. L. EASTES (*British Med. Jour., 1899, No. 2028, pp. 1311, 1312*).—The author records the results of microscopical and bacteriological examinations of 186 samples of milk "obtained from all parts of the [British] kingdom from medical officers of health, public institutions, and from private sources." While the primary object was to detect any tubercle bacilli present, the samples were also examined for other micro-organisms, the character of cells present, and the presence or absence of pus. It is stated that normal milk always contains leucocytes. When they are marked the milk should first be examined for colostrum corpuscles, and where these are absent the leucocytes are frequently associated with so-called mucous threads.

> "In hardly any case are these mucous threads present unaccompanied by pus cells, and the presence of such threads may usually be taken as corroborative proof that the leucocytosis is due to some inflammatory lesion. . . . The presence of an excess of leucocytes and this mucin-like substance constitutes 'muco' pus, and is a sign of the existence of an inflammatory lesion of the ducts of the udder, for it is in such lesions that the mucous material is excreted, and not from abscess cavities in the substance of the gland."

When an excess of leucocytes is found unaccompanied by this mucin-like material, which was the case in quite a number of samples, the nature of the leucocytosis is indicated by the presence of streptococci. When pus is present chains of cocci are found in the stained deposit, often in very large numbers, and frequently closely associated with the individual pus cells. Streptococci were found in nearly every sample of milk containing pus, while they were rarely found in milk not so contaminated. A streptococcus is known to be a cause of the infectious disease of the udder known as bovine mastitis, and the author cites a case of poisoning in human beings in which streptococci were the only pathogenic micro organisms found in the milk. He has "not the slightest doubt that unboiled milk containing streptococci is also responsible for some of the cases of infantile diarrhea and mortality."

The presence of blood is said to usually indicate the existence of an active inflammatory lesion, but not always, as it may be present in very early lactation due to physical causes.

The results of the study are summarized as follows:

> "Of 186 milks examined, tubercle bacilli were present in 11, and doubtfully in 2 others. One was doubtful because only one bacillus, morphologically correct, was found; the other because though of the right color, the beading was not apparent in any except one, and in that only imperfectly. In 47 there was pus, and muco pus was present in another 77. Both of these objectionable features were absent in 51 cases, and the question was undecided in the other 11. Blood was noted in 24 samples, absent in 77, and probably absent in 85. Streptococci were found in 106 cases, absent in 53, and undetermined in 27. Colostrum corpuscles were detected in 16 specimens. The percentages in the mixed milks work out as follows: 5.3 per cent contained tubercle bacilli; 30 per cent contained pus, and 48.7 per cent muco pus, these varieties being therefore present in 78.7 per cent of all mixed milks examined. They were absent in only 15 per cent and doubtful in the other 6.3 per cent. Streptococci were found in 75.2 per cent of the samples, absent in 15 per cent, and doubtful in the remaining 9.8 per cent.
>
> "Milk which contains pus or muco pus and streptococci is unfit for human consumption, but, unfortunately, according to my figures, this would entail condemning 80 per cent of the samples I have examined. . . . Should such milks also contain tubercle bacilli they should be unhesitatingly condemned as unfit for consumption in any form, for example, as butter, cheese, etc."

The virulence of the milk of cows which reacted with tuberculin but showed no clinical evidence of tuberculosis, OSTERTAG (*Ztschr. Fleisch. u. Milchhyg., 9 (1899), No. 9, pp. 168, 169*).—The investigation was made on a herd of 50 cows which was to be treated by the Bang method. The milk was examined for tubercle bacilli by bacteriological methods, intraperitoneal inoculation of the cream sediment according to Obermüller, and feeding the same to guinea pigs. It was found in the first series of experiments that the milk of 49 of the cows contained no tubercle bacilli. In the second series one of the inoculated animals was found when killed to be tuberculous, but a repetition with the same milk failed to produce any signs of tuberculosis. From this the author infers that the milk of cows which react may occasionally contain tubercle bacilli without necessarily being capable of communicating the disease through feeding. From his own experiments and those of others the author concludes that the milk of cows which react with tuberculin but show no clinical evidence of tuberculosis, can be regarded as uninjurious.

Contribution on the question of the infectiousness of the milk of tuberculous cows and the value of tuberculin inoculation, LYDIA RABINOWITSCH and W. KEMPNER (*Ztschr. Hyg. u. Infectionskrank., 31 (1899), No. 1, pp. 137-152*).—The authors review and summarize the literature to show that the milk of tuberculous cows has been found by inoculation experiments to be infectious in from 6 to 55 per cent of the cases, the greatest infectiousness being in cases of milk of cows which were either in advanced stages of generalized tuberculosis or had tuberculosis of the udder.

They studied the virulence of the milk of 15 cows which reacted with tuberculin. In the case of 10 cows the sediment of the cream when injected into guinea pigs produced symptoms of tuberculosis. Only one of the cows exhibited any clinical evidence of udder tuberculosis, and two others showed no evidence of any form of the disease.

The authors conclude that in the early stages of tuberculosis, in which no disease of the udder is apparent, as well as in the latent tuberculosis, which can only be detected by the tuberculin test, the milk may contain tubercle bacilli and is to be regared as suspicious. These results, the authors urge, indicate the diagnostic value of tuberculin, and lead them to pronounce it "the most important factor in the production of tubercle free milk."

In a review of the above paper, Ostertag (*Ztschr. Fleisch u. Milchhyg.*, *9* (*1899*), *No. 10*, *p. 192*) claims that the sweeping conclusions as to the danger from tuberculosis are not warranted. He points out that several of the cows used were in advanced stages of the disease, and that under the circumstances the air of the stable would contain large numbers of bacilli which might gain access to the milk from that source during milking. He objects also that no experiments were made in which the milk was fed to animals, that the turberculin test had been made 3 months previous to the examination of the milk, and that the clinical examination of the animals was not sufficiently thorough.

Remarks on Ostertag's paper on the virulence of milk of cows reacting with tuberculin, etc., and a reply to his criticisms, LYDIA RABINOWITSCH and W. KEMPNER (*Centbl. Bakt. u. Par.*, *1. Abt.*, *26* (*1899*), *No. 10*, *pp. 289–292*).—In this controversial article, the authors point out that the material fed by Ostertag, the skim milk, was not nearly as infectious as the cream, which usually contains a large proportion of the tubercle bacilli. They interpret some of Ostertag's results differently from what he did, and claim that the results of the first series of experiments are disputed by those of his second series. They hold, therefore, that his results are not opposed to theirs obtained on two occasions, namely, that in cases of latent tuberculosis, in which the tuberculin reaction is the only indication of the disease, the milk may contain tubercle bacilli.

In conclusion they reply to some criticisms of their previous paper by Ostertag.

On the Reichert figure of butter, J. H. STEBBINS, Jr. (*Jour. Amer. Chem. Soc.*, *21* (*1899*), *No. 10*, *pp. 938–940*).—The Reichert number is given for 317 samples of butter representing that exported to South American ports by 5 firms during the years 1897, 1898, and 1899. "The average of these 317 tests is 14.7. The highest figure obtained was 18.2, and the lowest figures found were 11.2, 11.4, and 11.7." The 3 samples showing the lowest numbers were all of winter butter, "the one giving the figure 11.2 having been kept so long that it was on the verge of becoming tallowy, while the other two were decidedly rancid."

The opinions of a number of chemists are cited as to the minimum Reichert number allowable, showing a considerable difference of opinion. The author favors placing the limit at 11.5, believing that it would not be prudent to go much below this, so as to cover such extreme cases as cited.

Examination of skim milk and buttermilk in Swedish creameries, N. ENGSTRÖM (*Meddel. K. Landtbr. Styr., 1898, No. 8, pp. 45–48*).—The skim milk and buttermilk in the creameries participating in the Swedish butter exhibitions were sampled and analyzed in the spring and the fall of 1898, 5-day composite samples being taken in all cases. The number of samples examined, styles of machines, and average fat content of the samples are shown below:

The results of the fat determinations in 452 samples of buttermilk from pasteurized and 78 samples from unpasteurized milk or cream are shown in the following statement, together with the losses of fat in the buttermilk from 100 kg. of sweet milk:

Examination of buttermilk in Swedish creameries, 1898.

	Fat content of buttermilk.		Fat in buttermilk from 100 kg. whole milk.	
	Pasteurized.	Not pasteurized.	Pasteurized.	Not pasteurized.
	Per cent.	*Per cent.*	*Kg.*	*Kg.*
Average	0.53	0.51	0.059	0.067
Maximum	1.54	1.52	.26	.22
Minimum	.21	.22	.02	.01
Average for all samples	0.53		0.060	

No unfavorable influence of the pasteurization on the churning was noticeable, the average losses in the buttermilk from 100 parts of whole milk being 0.059 part for pasteurization, against 0.067 part for nonpasteurization. The corresponding figures for 1897 were 0.047 and 0.057, respectively.—F. W. WOLL.

Experiments in butter making, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 34–40*).—Experiments relating to aeration, pasteurization, ripening of cream, churning, moisture in butter and composite samples for milk testing are reported.

In 17 comparisons of aerated and unaerated milk for butter making, the average scoring was slightly in favor of the butter made from the unaerated milk.

Butter made from pasteurized milk and pasteurized cream was compared with butter made from raw cream in 32 experiments carried on during the summer. There was very little difference in the quality of the butter made in the 3 ways. Pasteurization is considered of considerable value in winter when conditions are less favorable for the production of pure milk.

Butter was made from cream (1) ripened with broad and narrow surfaces exposed to the air, (2) ripened at 60° and 70 to 75° F., (3) stirred frequently while ripening and not stirred, and (4) ripened with 8 to 10 and 16 to 25 per cent starters. In each of the 4 series of experiments, including from 10 to 13 trials, the average results from the 2 methods compared were practically the same.

A comparison was made of churning butter into large lumps before drawing off the buttermilk, and of keeping in granular form until salted. When first made, the lump butter scored slightly higher than granular butter, but after keeping the order was reversed.

Analyses of the butter made in the above experiments are given in a table with notes referring especially to the moisture content. The result of experiments favored the use of ¾ oz. of salt per pound of butter rather than ¼, ½, or 1 oz.

Composite samples of daily milkings for periods of 1, 2, 3, and 4 weeks were tested for 4 months. The samples were preserved with a mixture of potassium bichromate and corrosive sublimate or with Geary tablets, and kept in duplicate in 2 rooms at temperatures of from 60 to 84° and 55 to 70°, respectively. The monthly tests were practically identical with the average of the 4 weekly tests and of the 2 semimonthly tests for the corresponding months. The test of the 3 weeks' sample was also identical with the average of the 3 weekly tests for the same time. The tests were alike for the samples kept at the different temperatures.

Report of Swedish butter exhibitions for the year 1898, N. ENGSTRÖM (*Meddel. K. Landtbr. Styr., 1898, No. 8, pp. 48*).—During 1898, 335 creameries, of which 135 were cooperative, took part in the periodical exhibitions, sending in all 1,303 tubs of butter, an increase of 18 creameries and of 89 tubs over the figures for 1897. The total expense of the exhibitions amounted to nearly $9,000, of which sum the Government contributed $2,680, and the various creameries participating in the exhibitions nearly the whole balance (annual dues per creamery, 50 kroner, or $13.40).

The average water content of the butter exhibited was 13.5 per cent, the range being from 10 to 22.4 per cent. The water content of 83.1 per cent of the butter lay between 12 and 14.9 per cent. Only 14 tubs leaked brine from the time of arrival until judged (a length of time corresponding to that required to bring the butter on the English market); the average leakage was 172 gm., the maximum, 470 gm.

Of the tubs scored 80.6 per cent were made from pasteurized cream and 15.7 per cent from raw cream, while 2.5 per cent was "Radiator" butter; 78.8 per cent of the creameries made pasteurized butter only, against 66.7 per cent in 1897. The creameries also making unpasteurized butter decreased from 16.4 to 9.3 per cent. Pure cultures were used exclusively in 30.8 per cent of the creameries, and at times in 11 per cent; while buttermilk starter was used in 49.5 per cent. Dividing the butter into 3 classes according to its score (perfect 15 points), the following table shows the proportion, in the case of each method of manufacture, which fell in each class:

Relative quality of butter made by different methods of manufacture.

Class.	Score.	Pasteurized.				Not pasteurized.			Radiator butter.
		Pure cultures.	Other starters.	Sweet cream.	Total.	Pure cultures.	Other starters.	Total.	
		Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
1	12 points and over	40.9	47.4	28.6	43.9	7.8	7.1	7.3	15.2
2	10–11.9 points	45.2	43.8	55.1	44.9	47.1	40.9	42.4	72.7
3	9.9 points or lower	13.9	8.8	16.3	11.2	45.1	52.0	50.3	12.1
	Average score (points)	11.27	11.43	11.01	11.34	9.44	9.61	9.57	10.89

All butter exhibited was examined twice during the year for boric acid preservatives, and in no case were such preservatives found.—F. W. WOLL.

Investigations of the formation of molds in storage butter, 1896–1898, R. GRIPENBERG (*Meddel. Mustiala Inst. Forsöksstat. Mejeriafd., Helsingfors, 1899, pp. 51, col. pls. 11*).—The report gives a full account of investigations conducted during 1896-1898 at the dairy division of the Mustiala Institute Experiment Station, for the purpose of studying the causes of moldy butter. The author made a thorough study of the relation of different kinds of parchment paper and butter tubs to mold formation, and through laboratory experiments and storage trials under practical conditions ascertained the factors that would favor the formation of molds in butter, as well as such as would prevent their appearance. The investigations show that earlier views as to the main causes of moldy butter are incorrect. Moldy butter, according to the author, is generally considered to be caused by the use of poor butter tubs, thin parchment paper, prolonged soaking of the tubs in water prior to the packing of the butter, or by leaving the packed and covered tubs standing in the same place for a long time. While it must be admitted that these conditions in a measure favor mold formation in butter, the work done shows conclusively that the appearance of molds is due primarily to infection. In view of the ease with which mold spores are carried about by air currents, and their general distribution, it may be assumed that this infection takes place as frequently in the creamery or dairy itself as later during the storage in butter cellars or storage rooms. Spores of the common mold fungi may also appear on the parchment paper.

It was shown that with a sufficient amount of moisture both the wood and the paper can sustain growths of the molds studied more in detail (principally *Penicillium crustaceum* and *Trichosporium collæ*). Only a very slow growth is made, however, especially when the supply of air is limited, but if this is ample, the temperature higher, and the butter serum penetrates the paper and the wood, the formation of mold will progress very rapidly. Common salt was found to inhibit the growth of molds in proportion to the amount of salt in solution, but even in brine containing 25 per cent of salt colonies of molds were able to grow, although very slowly. Molds were found even when the tubs were cleaned and steamed most carefully and the paper sterilized, showing that spores from the air must have fallen into the tub and adhered to its inner surface or to the paper. If the tubs have become infected with mold spores, mold formation is apparently greatly favored by a careless packing of the butter and by the use of leaky tubs.

The preventive measures against moldy butter which the author recommends are as follows:

(1) Removal of fungi or spores from the tubs by careful scrubbing and rinsing with water containing soda or common salt.

(2) Steaming the tubs 5 or 10 minutes, to kill any remaining organisms.

(3) Soaking the parchment paper in strong brine or steaming it.

(4) Protection of the interior of the tub, as well as the paper and the butter, from spores falling from the air or from the clothes of the butter maker.

(5) The use of as tight and as well-made tubs as possible, and by packing the butter with the greatest care, so that no empty spaces are formed between the butter and the side of the tub.

(6) During the warm season (or even to October 15) the tubs should be lined with heavy parchment paper, preferably Nos. 2, 3, or 4, or else two layers used, e. g. No. 4 on the outside and No. 7 next to the butter.

(7) Rubbing the inside of the tub with salt immediately before the butter is packed. To prevent the introduction of mold spores, the salt is placed in a warm oven for half an hour before being used, and then kept in a covered jar or glass vessel.

(8) Before shipping the packed butter, tubs are kept in as cold and dry place as possible, preferably at a temperature of 4 to 5° C (39 to 41° F).—F. W. WOLL.

Experiments in cheese making, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 40–64*).—A number of experiments, mainly in continuation of previous work (E. S. R., 10, p. 291), are reported.

Aeration of milk for cheese making (pp. 40, 41).—Thirteen experiments were made during July, September, and October, in each of which cheese was made from aerated and unaerated milk. The average scoring was in favor of the cheese made from the aerated milk. The results, however, are considered unsatisfactory, and the investigation is to be continued during 1899.

Relation of fat in milk to quantity and quality of cheese (pp. 41–52).—The principal results from 27 experiments made in 1898 are summarized in the following table:

Yield and quality of cheese from richer and poorer milk.

Group.	Fat content of milk.		Milk required to make 1 lb. of cheese.	Cheese produced from 1 lb. of fat in milk.	Fat content of whey.	Quality of the cheese.				
	Range.	Average.				Flavor (max. 35).	Closeness (max. 20).	Even color (max. 15).	Texture. (max. 20).	Average total score (max. 90).
	Per ct.	*Per ct.*	*Lbs.*	*Lbs.*	*Per ct*					
1	Below 3	2.92	11.650	2.94	0.133	31.00	16.66	13.66	16.66	77.98
2	3.00 to 3.50	3.14	11.598	2.74	.140	30.23	17.97	14.29	16.85	79.34
3	3.55 to 4.00	3.88	10.209	2.52	.189	30.74	18.16	14.20	17.56	80.66
4	4.05 to 4.50	4.21	9.504	2.49	.213	31.41	18.25	14.56	17.06	81.28
Average		3.57	10.675	2.62	.168					

"It will be noticed in the foregoing table (1) that less milk was required to make a pound of cheese as the percentage of fat increased; (2) that the pounds of cheese per pound of fat in the milk decreased with an increased percentage of fat in the milk; (3) the percentage of fat in the whey increased with an increase of the fat in the milk."

Cheese made from rich milk lost less in weight during one month in the curing room than cheese made from poor milk. In 3 trials the yield of cheese made from a mixture of rich and poor milk was slightly greater than the average yield of cheese made from the 2 milks separately.

Tables give a general summary of 250 experiments along this line made during 5 years. Following are some of the conclusions:

"(1) There is an increased yield of cheese per 1,000 lbs. of milk as the percentage of fat increases An increase of 1 per cent (3.2 to 4.2) in the fat of the milk caused an average increase of nearly 16.5 lbs. of cheese per 1,000 lbs. milk, which at 8 cts. per pound gives an added value of $1.32 per 1,000 lbs. of milk testing 4.2 per cent fat as compared with the value of 1,000 lbs. of 3.2 per cent milk.

"(2) As the percentage of fat in the milk increased there was a gradual decrease in the pounds of cheese made per pound of fat in the milk. Milk testing 3.2 per cent fat produced an average of 2.8 lbs. cheese per pound fat in the milk, while milk testing 1.2 per cent fat yielded an average of 2.5 lbs. cheese per pound of fat in the milk.

"(3) The yield of cheese per pound of fat and casein, the latter estimated by adding 2 to the percentage of fat, ranged from 1.7 to 1.8 lbs. . . . As the yield of cheese is slightly less per pound of fat and casein in the richer milk as compared with the poorer, this system gives a slight advantage to the richer milk when compared with the actual cheese capacity of the two. This is well.

"(4) The experiments prove that not only is the percentage of fat higher in the whey from rich milk, but the total loss of fat per 1,000 lbs. of milk and per 100 lbs. of cured cheese is greater from the rich milk. There was not much difference in the loss of casein in the whey from rich and poor milk.

> "(5) Cheese made from rich milk lost less in curing than did cheese made from poor or medium milk.
>
> "(6) The average of the 5 years' scoring does not show very much difference in the quality of the cheese made from the milk containing the different percentages of fat. In individual cases there was a marked difference in the quality, but when all was averaged this difference largely disappeared. The extreme difference in total points scored in the groups was 2.27 points in favor of the richer milk. The percentage of fat in normal milk is but a small factor in determining the quality of the cheese which is made from it, so long as the fat is about 3.5 per cent."

The application of the results to methods of paying patrons is discussed, the author advocating the method in which the casein is taken account of by adding 2 to the percentage of fat.

> "Our 5 years' experiments prove that this system comes nearest to the actual value of the cheese produced, though it still places a slight premium on the butter fat. It encourages the production of good milk, and at the same time does not discourage the majority of patrons who have average milk, and who are apt to envy those patrons whose cows give a small amount of rich milk and draw a disproportionately large share of the proceeds of cheese sales when the money is divided on the basis of the fat alone."

Effect of setting milk at different temperatures (pp. 52, 53).—In 26 experiments made during September, October, and November, the effect of setting milk at 86° F. was compared with setting at temperatures ranging from 76 to 96°. When set below 80°, the time from setting to dipping and from dipping to salting was increased less than in previous experiments (E. S. R., 9, p. 483). A smaller yield of cheese was obtained from setting at temperatures below 86°. No difference in quality of cheese from setting at different temperatures was shown by the score.

Effect of different quantities of rennet (pp. 55, 56).—Results of experiments in 1898 are given, and conclusions are drawn from 4 years' work:

> "(1) Less than 3 oz. of standard rennet per 1,000 lbs. of milk causes a loss of fat in the whey much greater than is the case by using over 3 oz. of rennet. In the experiments for 1898, where 1 to 2 oz. of rennet was used, the percentage of fat in the whey was 0.45 and 0.30, whereas when a larger quantity was used the fat in the whey was seldom over 0.15 per cent.
>
> "(2) The length of time from setting to dipping and from dipping to salting was much the same whether a large or a small quantity of rennet was used.
>
> "(3) When less than 2 oz. of rennet per 1,000 lbs. of milk was used, the yield of cheese was considerably lessened; but an extra large quantity did not always give an increased yield, though it did in some cases, especially in 1897.
>
> "(4) The highest scoring cheeses were made by using about 3 oz. of standard rennet per 1,000 lbs. of milk.
>
> "(5) The time required for coagulation decreased as the quantity of rennet was increased.
>
> "(6) Cheese having a large quantity of rennet matured more quickly than that made by using a small quantity of rennet in the milk.
>
> "(7) We have endeavored to deduce a law for the effect of rennet on the time required for coagulation, but many difficulties are met, such as the difference in the ripeness of milk, and a difference in the susceptibility of milk for rennet influence. However, roughly speaking, we may say that the average of 4 years' experiments indicate that an increase of from 1 to 2 oz. per 1,000 lbs. of milk decreases the time

for coagulation about 30 minutes; from 2 to 3 oz. the time is decreased 10 minutes; from 3 to 4 oz. the time is decreased 7 minutes; and above 4 oz. the time is decreased an average of about 3 minutes for each increase of 1 oz. of rennet per 1,000 lbs. milk."

Effect of dipping at different stages of acid (pp. 55, 56).—The following conclusions are drawn from experiments made during 4 years:

"(1) Curds dipped with one-eighth to one-quarter of an inch as shown on the hot iron remained less time in the whey than those allowed to develop one-half to one inch of acid, but they took a longer time to mature after dipping before they were ready to salt. The whole length of time from setting to salting was much the same, whether curds were dipped early or late. There is no gain in time by leaving curds in the whey too long.

"(2) There was not a great deal of difference in the yield of cheese from early or late dipping. What difference there was was in favor of early dipping—one-eighth to one-quarter inch acid.

"(3) The loss of fat in the whey first drawn was practically the same in both cases; but the percentage of fat in the whey drippings was, in nearly every case, higher from the curds allowed to develop over one-quarter of an inch of acid in the whey. This explains the harsh nature of acidy cheese. It is, to some extent at least, due to the loss of butter fat from the curds after dipping.

"(4) The quality of the cheese in nearly every case was better from the early dipped curds. Curds allowed to remain in the whey until they show over half an inch of acid are harsh in texture, 'cut' in color, and usually sour to the taste."

Putting curds to press at different temperatures (pp. 56, 57).—Ten experiments were made, in which curd was put to press at temperatures ranging from 60 to 94° F. The highest-scoring cheese was obtained from curd pressed at 82°, and the next highest from curd pressed at 94°. The results of these and previous experiments show that "quite a wide range in temperature may be allowed for putting curds to press, as long as the press room is kept moderately warm to enable the cheese to form a proper rind."

Curing cheese at different temperatures (pp. 57–62).—The effect of temperature in curing cheese was studied in 18 experiments made from June to October, with the following results:

"(1) The cheese lost considerably more during 1 month's curing when kept at a comparatively high temperature. This was true for each month during the experiments and also for the season. The average percentage of shrinkage during the season for 1 month, in cheese weighing about 30 lbs., cured at 60°, was 3.40 per cent; cheese cured at 66° lost 3.85 per cent in weight, and cheese cured at 69° lost 4.31 per cent.

"(2) The quality of the cheese was very much better by curing at 60°. The average score for the season of cheese made in the college dairy was nearly 3 points in favor of cheese cured at 60° as compared with similar cheese cured at 66°, and 5 points higher compared with those cured at 69°. The difference was more marked still in September and October cheese. The flavor was very much better in the cheese cured at 60°, and the texture was a marked improvement. Cheeses cured at a high temperature go off in flavor quickly and have a sandy or mealy texture. Cheese made in October and cured at 60° was pronounced as being worth from 1 to 2 cts. more per pound than similar cheese cured at 70 to 75°. Cheese cured at the lower temperature had very much better keeping quality."

Notes are given on the growth of mold at the different temperatures and on the means employed for preventing it.

Mottled cheese (pp. 62–64).—Starters prepared from mottled cheese, cultures from the bacteriological laboratory originally from the same source, and sour whey were used in 45 experiments made during April, May, August, and September. The conclusions drawn from the results follow:

"(1) Mottled cheese may spread from one day's make to another, but it is most likely to do so from or through the starter.

"(2) The mottles usually appeared in from 2 to 4 weeks after the cheese was made.

"(3) Sometimes a starter produced mottles, and sometimes the same starter did not.

"(4) Pasteurizing the whole milk used in the vat did not prevent mottling.

"(5) In no case did mottles appear in the white cheese made from any of the starters.

"(6) The cultures sent from the bacteriological laboratory did not cause the mottling to any extent. In 1 or 2 cases there was a slight waviness or mottling.

"(7) In some cases the mottles appeared quite strongly and then disappeared after a time. In some cases the mottling appeared in spots through the cheese. A cheese made August 22 was examined on November 29, and the first plug showed no mottles. Out of 5 plugs drawn from different parts of the cheese 2 of them showed mottling.

"(8) Starters made from the whey tank produced mottling of the cheese and a very bad flavor. It is probable that the difficulty is caused in some cases by taking whey home in the milk cans and then sending the milk to the factory in these cans not properly washed and scalded."

Excelsior cheese coating (p. 64).—A test was made of this material, which is claimed to prevent the loss of weight in curing, improve the quality of the cheese, and prevent the growth of mold. It was found to lessen the loss from shrinkage, but did not improve the quality. It is considered doubtful if the results would warrant the expense and trouble in using.

Some investigations in dairy physics, J. B. REYNOLDS (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 5–7*).—Determinations are given of the rate of expansion of water, skim milk, whole milk, and cream, and of the relative rates of cooling and heating of butter, cream, whole milk, and skim milk, made in an investigation bearing on the theory of separation of cream in deep setting. The methods employed are described and notes given on nonconcordant results relative to the specific heat of milk and cream obtained by different methods. In discussing the rate of expansion of the different substances the author says:

"It is evident that the greater the amount of butter fat or other solids in the milk the more uniform is the expansion. Cream has nearly the same rate of expansion at all temperatures. Pure water increases its rate of expansion quite rapidly with increase of temperature. A second and more important point in the results is in their relation to the separation of cream by the deep setting system. The rate of expansion or of contraction between the limits 68 to 50° F. is, for serum, 0.000175; for cream, 0.000582. The cream, therefore, contracts about 3½ times as fast as the serum within the limits of temperature usual for the deep setting method. Hence, while the serum is always heavier than the cream, the latter very rapidly approaches the specific gravity of the former as they cool. They are therefore becoming more and more nearly equal in weight; so that whatever is the cause of the more rapid separation by the cooling system, it can not be due to an increase in the difference of specific gravity, since the opposite is the case."

Handling dairy cows, G. H. GURLER (*Creamery Jour., 10 (1899), No. 121, pp. 8, 9*).—Brief notes on the care of dairy cows.

Some practical hints on dairying, G. S. THOMPSON (*Jour. Agr. and Ind. South Australia, 3 (1899), No. 4, pp. 354–366*).—Notes are given on the selection of a dairy herd, milk supply, feeding of cows, milk and milking, cream ripening and churning, cheese making, and the symptoms and treatment of a number of diseases of cows.

Dairy stock, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 66–70*).—A record of the dairy herd showing the yield and cost of milk, butter, and cheese for each cow is given for 3 years.

Some Jersey types, M. B. WOOD (*Dairy Reporter, 3 (1899), No. 32, pp. 502, 503, figs. 15*).—Brief historical notes on a number of individuals.

Oats and peas and oats and tares as soiling crops for milch cows, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 78–80*).—Two cows were fed oats and peas for 11 days and 2 were fed oats and tares for the same time. The rations were then reversed and the feeding was continued for 11 days. The yields of milk during the last 6 days of each period are summarized. The results are considered as showing that there is very little difference if any between oats and peas and oats and tares for milk production.

Sugar beets vs. mangels for milch cows, G. E. DAY (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, p. 80*).—Two cows were fed sugar beets and 2 were fed mangels for 2 weeks. The rations were then changed and fed for 2 weeks longer The yields of milk are given. The results are slightly in favor of mangels, but are not considered conclusive.

Influence of feed on quantity and quality of milk, F. C. CURTISS (*Ontario Agr. and Expt. Union Rpt. 1898, pp. 50–56*).—A brief discussion of the subject with the following conclusion: "Feed is in various ways an extremely important factor that must be reckoned with in its effect on both the quantity and quality of dairy products, though the immediate modification in quality that may be attributed to feed is comparatively slight."

The acid test for milk, W. J. SPILLMAN (*Dairy and Creamery, 1 (1899), No. 21, p. 6; Amer. Cheesemaker, 14 (1899), No. 165, p. 4*).—A brief popular discussion on the practical value of determining the acidity or milk and cream.

Bacteriology and the dairy industry, D. ROBB (*Dairy, 11 (1899), Nos. 130, pp. 299–301; 131, pp. 358–360*).—This treats popularly of the discovery and morphology of bacteria, their origin and action in milk, and their use in butter and cheese making.

Bacteria in butter and in other dairy products, WEISSENFELD (*Berlin. Klin. Wchnschr., 36 (1899), No. 18, pp. 1053–1055*).—Tests were made with 32 samples of butter, in which the tubercle bacillus was found in 10 cases. Nutrose, eucasin, calcium phosphate-casein, and plasmon were also investigated, and found to contain quantities of cocci and diplococci.

New bacilli causing butyric fermentation in market milk, A. SCHATTENFROH and R. GRASSBERGER (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 7, pp. 209–211*).—The physiological-chemical behavior of three forms is described, which were found in market milk. They cause a vigorous fermentation in sterilized milk, with the production of butyric acid, but not butyric alcohol. The casein is precipitated but not peptonized.

The milk of the dairies of Genoa in relation to tuberculosis, A. MASSONE (*Riv. Ig. e San. Pubb., Roma, 9 (1898), No. 7, pp. 250–252*).—The milk from the city cows was found less infected with tuberculosis than that from the surrounding countries.

Part played by moisture in the curing room, S. J. TAYLOR (*Amer. Cheesemaker, 14 (1899), No. 166, p. 6*).—A popular discussion on the construction of curing rooms with reference to the control of temperature and moisture.

Cheddar cheese, F. J. LLOYD (*Amer. Cheesemaker, 14 (1899), No. 165, pp. 1, 2*).—A discussion of conditions essential to its manufacture in England.

Cooperative experiments in curing cheese, H. H. DEAN (*Ontario Agr. and Expt. Union Rpt. 1898, pp. 45–48*).—The results of a number of experiments relating to the effects of temperature in curing cheese are summarized in tabular form and directions are given for the determination of moisture in cheese curing rooms. It was found that cheese cured at 60 to 65° F. lost about 1 per cent less by shrinking and was of superior quality as compared with similar cheese cured at 70 to 80°.

Miscellaneous dairy notes, H. H. DEAN (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 70–74*).—Notes are given on milk tests at fairs and farms, thermometers and hygrometers for the dairy and curing room, testing new churns, construction of the curing room, dairy exhibit at the industrial fair at Toronto, and fly mixtures for cows.

VETERINARY SCIENCE AND PRACTICE.

Contribution to the study of the origin of antityphic substances, L. DEUTSCH (*Ann. Inst. Pasteur, 13 (1899), No. 9, pp. 689–727*).—In this article the author reports the results of studies undertaken to demonstrate the method and place of formation of substances which are antagonistic to the development of typhus, and the results of his study of the formation of agglutinating substances under similar circumstances. The results of the author's work may be briefly summarized as follows: A single intraperitoneal injection of the typhus culture induced the formation of the antagonistic substances in guinea pigs. Antityphic properties appeared in the serum about the fourth or fifth day, increased so that the maximum was reached about the eleventh or twelfth day, and then gradually diminished, but could, however, be demonstrated as present for fully a month after the injection. The antityphic property is rather considerable in the liver, kidneys, and suprarenal capsules. In from one fourth to one-fifth of the cases the bone marrow was more active than the serum, and this was true of the spleen in one-half of the cases. The lymphoid organs are in some manner connected with the formation of the antagonizing substances, this connection being demonstrated by a large number of experimental facts.

With regard to the formation of agglutinating substances, the following were the main results obtained: An intraperitoneal injection of a heated typhus culture induced the appearance of an agglutinating power in the serum of the guinea pig. The appearance and development of this power is subject to the same laws as the development of the antagonizing substances. The liver, kidneys, and suprarenal capsules of immunized animals contain only traces of agglutinins. The lungs may be considered as the only organ of the guinea pig which usually possesses a greater agglutinating power than the serum.

The relative virulence for the domestic animals of human and bovine tubercle, R. R. DINWIDDIE (*Arkansas Sta. Bul. 57, pp. 21–95*).—The purpose of the experiments which are recorded in this bulletin was to determine certain factors in the question of the transmission of tuberculosis from man to animals and from animals to man. The first part of the bulletin consists of a review of some of the literature on the subject of tuberculosis with a brief bibliography.

Experiments were made upon 20 calves, 16 pigs, 2 sheep, 16 chickens, and several guinea pigs and rabbits. Experiments were conducted in 2 ways, by feeding the tubercle material and by intraperitoneal inoculations. The majority of the experiments were comparative in that a part of the experiment animals were fed or inoculated with tuberculous human sputum and another part were fed or inoculated with tuberculous material of bovine origin.

In the feeding experiments the author made use of 4 cattle, 6 pigs, and 6 chickens. The tuberculous material was fed in small, frequently repeated doses, either mixed with milk or dry with bran. The 4 cattle consisted of 2 calves and 2 two year olds. The minimum dose of human tuberculous sputum was 10 cc. and the maximum 60 cc. The feeding period extended from August to October, 1896. On December 29 all 4 failed to respond to the tuberculin test. On March 8, 1897, all 4 animals were killed and proved to be entirely free from tuberculosis. Six pigs received 20 doses of sputum, and when killed, 10 months after the beginning of the experiment, 2 of them exhibited slight tubercular lesions. No tubercular infection was produced in chickens by the feeding experiments.

In the inoculation experiments, 8 calves and 4 pigs received intraperitoneal inoculations of either human or bovine tubercle materials. The human tubercle material was from pulmonary tuberculosis. The bovine material came from caseous, degenerated lungs or thoracic lymph glands. Besides the inoculation experiments with tuberculous material, such as has been described, other intraperitoneal inoculations were made with artificial cultures of tubercle bacilli, these experiments being conducted upon calves, chickens, pigs, and sheep. Artificial cultures were also fed to calves and pigs for experimental purposes.

The results of the experiments may be brought together in the following statements: Feeding the tuberculous sputum of man to calves gave negative results. Intratracheal inoculations of sputum and bovine tubercle material as well as the intraperitoneal inoculations of the same two sorts of material gave results which indicate that the tuberculous material of bovine origin acts more virulently upon cattle than the tuberculous sputum of man. The feeding of tuberculous sputum to 6 pigs resulted in a slight infection of 2 of them. The intraperitoneal inoculation of sputum and bovine tubercle in 4 pigs resulted in tuberculous infection of both pigs which were inoculated with the bovine material and of 1 which was inoculated with the human material. An intraperitoneal inoculation of pure cultures of human origin in the pig produced no lesions. Similar inoculation of bovine origin in 2 pigs gave in one a generalized and in the other a localized tubercular infection.

In the sheep intraabdominal inoculations of pure cultures of bovine origin gave a more virulent form of the disease than the inoculation of pure cultures of human origin. Intraabdominal inoculations of sputum and of bovine tubercle material gave negative results in chickens.

With regard to the relative susceptibility of different animals the results obtained may be summarized as follows: Bovine tubercle is more virulent than human tubercle for cattle, sheep, goats, and rabbits; while horses, pigs, cats, and dogs seem to be equally susceptible to both varieties. The author believes that the former result can not be interpreted as lending weight to the theory that human and bovine tubercle are 2 distinct varieties. The fact that the disease develops differently in cattle and in man is interpreted by the author as meaning that the 2 organisms react differently to the same pathogenic agent. The author's experiments lend weight to the theory that human tuberculosis is not a serious source of danger in the infection of cattle, and that the majority of cases of infection in cattle come of bovine origin. The experiments recorded in this bulletin are not intended to throw any light upon the question of the danger of the infection of human beings by the use of tuberculous meat and milk.

Bovine tuberculosis, C. E. THORNE (*Ohio Sta. Bul. 108, pp. 287–372, figs. 9*).—This bulletin contains a general account of the nature of tuberculosis, of the properties of the tuberculin test, and of the method for applying this test. Tuberculosis having broken out in the station herd, the animals were all tested with tuberculin furnished by the Bureau of Animal Industry of this Department. Details are given of the temperature records during the tuberculin tests and of the *post-mortem* examinations in those cases which were slaughtered. In discussing the effects of the tuberculin test upon the animals, the author concludes that the tests conducted at the station "can not be interpreted as supporting the theory that the tuberculin test will arouse dormant cases of tuberculosis and start the disease into a more active form."

The author discusses the problem of the disposal of the meat and other products of tuberculous animals, and believes that the experiments conducted at the station indicate that cattle may be useful for several years after infection with tuberculosis. The tuberculin test may be repeated as often as once a month without harm to the animal and even in some cases with an apparent curative effect. In herds which are not suspected of being tuberculous the test need not be repeated oftener than once in 6 months.

Regarding the prevalence of the disease in swine, 7 Berkshire pigs from a sow which was believed to be free from tuberculosis were chosen for experiment. A portion of them were fed with pasteurized milk and another portion with unpasteurized milk. At the end of the experiment, however, it was found that all the pigs were thoroughly infected with tuberculosis. Later it was discovered that the sow was also suffering from the disease, and that there was a large tubercular mass in the udder. It would appear that all the pigs had been infected from that source.

After a review of the literature which bears upon the prevalence of tuberculosis in different countries, and in the States of this country, the author states his belief that it will be possible to eradicate the disease completely from any herd, or even from the whole State.

A large portion of the bulletin is occupied with a discussion of the answers to lists of questions which were distributed among the health officers and veterinarians of the State. These questions had regard to the prevalence of tuberculosis in dairy cattle, the extent of the application of the tuberculin test and of meat and milk inspection. The answers indicate that there have been discovered numerous cases of tuberculosis in cattle furnishing milk to cities, and that the tuberculin test is not applied as extensively in the State as it should be. The author discusses in some detail the relationship of bovine tuberculosis to the public health, and the question of the identity of the bacillus in the human and bovine form of the disease. In this discussion statistics from census reports and the scientific literature on the subject are drawn upon freely. In regard to the question of the possible hereditary origin of tuberculosis, the author believes that nearly all, if not quite all, cases of tuberculosis, arise after birth from external infection, or are at least congenital in contradistinction to hereditary. Tuberculosis has been experimentally produced in calves at the Ohio Station by feeding the milk from tuberculous cows.

The author considers the question as to whether it is safer to use the milk of one cow or mixed milk for infants. His opinions are based upon the testimony of numerous physicians of the State, 339 reports having been made in reply to a series of questions from the station. A majority of the physicians with country practice were of the opinion that the milk from one cow is better than mixed milk, whereas the opposite opinion was held by a majority of physicians with city practice. This difference of opinion, the author believes, is due entirely to the difference of environment, it being practically impossible for any except wealthy persons to keep a cow in a city under normal conditions. From the replies of the physicians of the State, as well as from other statistics compiled by the author, it is stated that probably a large proportion of cases of death from intestinal trouble of infants is directly attributable to the use of tuberculous milk. The physicians consulted agreed that cow's milk is safer than mother's milk if the mother is tuberculous.

The author has compiled statistics which would indicate that in Ohio the number of deaths from tuberculosis is not decreasing. It has been shown by statistical methods in many countries that bovine tuberculosis is increasing at the same time that human tuberculosis is decreasing, and it has been assumed from this inverse proportion that perhaps bovine and human tuberculosis are not identical diseases. The author believes the balance of evidence is in favor of the belief that the bovine and human forms of tuberculosis are not distinct diseases, but that there is sufficient evidence for us to believe that tuberculosis is produced in the lower animals by inoculation with material from human subjects, and that man has frequently contracted the disease from tuberculosis material of bovine origin.

Investigations on the nature and etiology of milk fever, H. Van de Velde (*Monatsh. Prakt. Thierh., 11 (1899), No. 3, pp. 97–113, fig. 1*).—In studying this disease the author made a careful record of the clinical symptoms and peculiarities of different cases, and examined microscopically and by means of cultures, the various micro-organisms which he found in connection with each case. In all cases where the disease resulted in death, a thorough *post-mortem* was made. Experimental inoculations were made upon other animals and antistreptococcic sera were employed for the purpose of determining their effect in checking the activity of the pathogenic organism.

The results of the author's investigations may be summarized as follows: Of the 14 cases of milk fever which were observed, the majority were of the paralytic form, and 7 of these cases were fatal. The organisms which were most frequently found were streptococci, staphylococci, and coli bacilli. Milk fever may be caused by simple infection, by one organism, or by mixed infection by several organisms. In simple infections, streptococcus was more frequently the cause of the disease, and the same organism seemed to be the most important one in cases of mixed infection. The streptococci, which were determined as the cause of milk fever, were not to be distinguished in any way from those which were found in cases of puerperal septicæmia of man.

Report of the professor of veterinary science, J. H. Reed (*Ontario Agr. Col. and Expt. Farm Rpt. 1898, pp. 31, 32*).—A brief report of the diseases treated during the year.

Report of the verterinary division of the ministry of internal affairs for 1896 (*Otchet Veterinarnago Otdyeleniya Ministerstva Vnutrennikh dyel. St. Petersburg, 1899, pp. 544*).—A statistical record of the various diseases of domesticated animals in Russia.

Report on the veterinary service and meat inspection in Norway for 1897 (*Beretning om Veterinärväsenet og Kjödkontrollen i Norge. Christiania: Director Civil Veterinary Service, 1899, pp. 241*).—A report, with extensive statistical tables, on anthrax, blackleg, hog cholera, swine plague, tuberculosis, and other diseases of domesticated animals in Norway.

Twenty-fifth annual report of the Royal Institution for the Cultivation of Cow-pox Virus at the Royal Veterinary School of Utrecht, with an appendix of the results obtained in the vaccination of animals, on the origin of the Royal Cow-pox Institution, and its activity during the first twenty-five years (1873 to 1897), A. W. H. Wirtz (*Utrecht, 1899, pp. XX + 92*).—This report contains a historical account of the institution and a detailed description of the method of cultivating cow-pox virus, including a discussion of the effects upon the calves which were used for this purpose.

The rôle of insects in spreading infectious diseases of man and animals, R. Abel (*Hyg. Rundschau, 9 (1899), No. 21, pp. 1065–1070*).—This paper contains a number of observations on insects as carriers of disease and is supplementary to Nuttall's work on this same subject.

On the etiology of tetanus, R. MORSELLI (*Gior. R. Soc. Accad. Vet. Ital., 48 (1899), No. 40, pp. 946–948*).—Observations on cases of traumatic and other forms of tetanus.

Tetanolysin, T. MADSEN (*Ztschr. Hyg. u. Infectionskrank., 32 (1899), No. 2, pp. 214–238, figs. 4*).—In cultures of the tetanus bacillus tetanolysin is formed, for which there is a specific antitoxin, known as antilysin. The effects of the lysin and its antipathetic substance can be readily determined by staining methods. Tetanolysin combines with the red blood corpuscles.

Heredity, disposition, and immunity in connection with tuberculosis, F. LÖFFLER (*Arch. Wiss. u. Prakt. Thierh., 25 (1899), No. 6, pp. 427–442*).—An account of the diseases which predispose to tuberculosis, and a study of the hereditary factor.

The methods of transmission of tuberculosis, C. FRÄNKEL (*Arch. Wiss. u. Prakt. Thierh., 25 (1899), No. 6, pp. 396–417*).—A thorough study of the various ways by which the disease is communicated from animal to animal or from man to man.

The tubercle bacillus and its relationship to tuberculosis, FLÜGGE (*Arch. Wiss. u. Prakt. Thierh., 25 (1899), No. 6, pp. 385–395*).—The tubercle bacillus is an obligate parasite and is found in the outer world only in consequence of its escape from the tubercular material of animals and man.

The localization of the tubercle bacillus after direct inoculation into the left ventricle, P. L. FRIEDRICH and H. NÖSSKE (*Beitr. Path. Anat. u. Allg. Path., 26 (1899), No. 3, pp. 470–510, pl. 1*).—The course of the disease under these circumstances was shown to vary exceedingly in different cases and to be influenced largely by the presence of other organisms mixed with the tubercle bacillus.

The growth of tubercle bacilli upon culture media containing potato, E. TOMASCZEVSKI (*Ztschr. Hyg. u. Infectionskrank., 32 (1899), No. 2, pp. 246–267.*—The results published by Lubinski and Sander are not supported by the author's observations. Occasionally a luxuriant growth of tubercle bacilli took place upon potato cultures, but this was the exception. No decided change was noticed even after three or four generations of such cultures. On the contrary, an unfavorable influence was manifested.

On the acid-proof bacteria of the tubercle-bacillus group, G. MAYER (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 11–12, pp. 321–336, figs. 5*).—A study of several of these bacteria with special regard to the differences shown in their growth and in their pathogenic reaction.

Mixed infection in tuberculosis, R. PFEIFFER (*Arch. Wiss. u. Prakt. Thierh., 25 (1899), No. 6, pp. 418–426*).—An account of the other pathogenic organisms which are found in connection with tubercular infection.

Experiments on the danger from meat of tuberculous animals, D. VAN DER SLUYS (*Ztschr. Fleisch u. Milchhyg., 10 (1899), No. 1, pp. 8–12*).—Out of 10 young pigs fed with tuberculous meat, 3 became infected with tuberculosis.

The administrative control of tuberculosis, R. T. THORNE (*London: Baillière, Tindall & Cox, 1899, pp. 73, figs. 2*).—In this book a series of lectures by the author is brought together which deal with the methods for regulating and controlling the spread of human and bovine tuberculosis.

Tuberculosis in cattle, D. MCEACHRON (*Queensland Agr. Jour., 5 (1899), No. 3, pp. 305–310*).—A brief general discussion of problems connected with the reduction of this disease.

Bovine tuberculosis in Argentine Republic, SIVORI (*Rec. Med. Vet., Paris, 8. ser., 6 (1899), No. 19, pp. 603–607*).—A discussion of the prevalence of tuberculosis as found in milch cows and in beef animals.

Bovine tuberculosis (*La tuberculosis en el ganada bovino. Argentine Republic, Dept. Agr., 1899, pp. 15*).—A discussion of means of contagion and diagnosis of tuberculosis and a report of results obtained by the application of the tuberculin test.

Report of an inquiry into the prevalence of tuberculosis in dairy cows as revealed by the tuberculin test, W. AXE (*Jour. British Dairy Farmers' Assoc., 14*

(1899), No. 3, pp. 245–259).—Gives the proportion of reacting animals of different breeds. Special attention was given in these experiments to an examination of the udders.

Tuberculosis in cattle, S. S. Cameron (*Queensland Agr. Jour., 5 (1899), No. 1, pp. 71–81*).—This paper is a report of tuberculin tests made in Victoria. Two hundred and seventy-six cattle were tested and 9 per cent reacted. All the animals which reacted were shown by *post-mortem* examinations to be tuberculous.

Tuberculosis in cattle and its control, O. E. Stenström (*Milch Ztg., 28 (1899), Nos. 29, pp. 449, 450; 31, pp. 483, 484; 32, pp. 499–501*).—A study of the relative susceptibility of different ages, sex, and races of cattle to tuberculosis.

The measures to be taken against tuberculosis of the domesticated animals, B. Bang (*Jour. Comp. Path. and Ther., 12 (1899), No. 3, pp. 189–205*).—Reports extensive tuberculin tests which indicate that tuberculosis is not usually a congenital disease. For control of tuberculosis, it is necessary to prevent the infection of calves to kill badly diseased animals, to give special attention to tuberculosis of the udder, and to heat the milk which is returned from public creameries after separation.

Inoculation as a preventive of tick fever, F. Gostling (*Queensland Agr. Jour., 5 (1899), No. 1, pp. 86–89*).—Inoculation furnishes effective prophylaxis. In cattle 2 years of age the loss from inoculation amounts to 1 per cent, while in older cattle it may reach 5 per cent. The inoculation of pregnant animals did not produce a greater mortality than was shown in other cattle.

Observations on ticks and tick fever at the Indooroopilly Experiment· Station and at St. Helena, C. J. Pound (*Queensland Agr. Jour., 5 (1899), No. 1, pp. 81–86, pls. 2*).—Experiments conducted upon inoculated and uninoculated cattle showed that the ticks are not destroyed and the spread of the fever is not checked during the winter months. Experiments demonstrated that inoculation when properly performed is not attended with serious loss and is an effective method of securing immunity to the fever.

Anthrax in West Gothland, A. G. Florén (*Svensk Vet. Tidskr., 4 (1899), No. 7, pp. 308–311*).—This is a report on the study of the origin of the infection which caused a considerable loss.

Effect of injection of bile from animals which died of anthrax, B. Morpurgo (*Riv. Ig. e San. Pubb., Roma, 9 (1898), No. 1, pp. 9–14*).—The injection of bile did not cause infection nor did it produce immunity.

Memorandum upon protective inoculation against anthrax, F. Tidswell (*Agr. Gaz. New South Wales, 10 (1899), No. 9, pp. 883–891*).—Inoculation of sheep against anthrax in New South Wales caused a considerable number of deaths, but was generally successful.

The danger from anthrax in working with animal hair and the preventive measures to be adopted, Kübler (*Arb. K. Gesundheitsamte, 15 (1899), No. 3, pp. 456–475*).—Treatment of the hair with boiling water or steam gave good results. Potassium permanganate in a 2 per cent solution is effective in destroying the anthrax bacillus if the treatment is continued for one-half hour. Live steam proved to be the most reliable disinfectant.

Cattle plague in South Africa, P. M. Edgar (*Veterinarian, 72 (1899), No. 862, pp. 707–718*).—An etiological and pathological study of the disease.

Vaccination against blackleg, S. Arloing (*Jour. Med. Vet. et Zootech, 5. ser., 3 (1899), pp. 573–586*).—A discussion of the precautions to be observed in order to prevent accidents and secure effective protection against the disease.

Observations on contagious foot-and-mouth disease and its control, A. G Florén (*Svensk Vet. Tidskr., 4 (1899), No. 6, pp. 231–242; 7, pp. 269–299*).—This article contains a description of the course of the disease in sheep, goats, cattle, hogs, and man. Experiments were conducted in making lymph inoculations for producing immunity.

Inoculations with Seraphthin, H. REICHENBACH (*Schweiz. Arch. Thierh., 41 (1899), No. 5, pp. 213–216*).—From experiments on 50 cattle this substance was found to be worthless as a preventive of foot-and-mouth disease.

A report on the disease affecting cattle in the Moruya district, J. D. STEWART (*Agr. Gaz. New South Wales, 10 (1899), No. 11, pp. 1205–1209, pl. 1*).—Upon investigation of this disease, it was found that the cattle had been poisoned by eating *Macrozamia spiralis.*

The dying of young calves, H. M. SCHMIDT (*Landw. Wchnbl. Schleswig-Holstein, 49 (1899), No. 41, pp. 749–753*).—Recommends the thorough disinfection of the cows with a solution of corrosive sublimate.

Milk fever and the new treatment, L. PEARSON (*Hoard's Dairyman, 30 (1899), No. 37, pp. 738, 739*).—Experiments with the iodid of potash method.

Carbolic acid and glycerin in the treatment of milk fever, C. FABBRETTI (*Gior. R. Soc. Accad. Vet. Ital., 48 (1899), No. 42, pp. 985–989*).

Veterinary notes, R. G. SAUNDERS (*Colonial Col. Mag., 5 (1899), No. 5, pp. 301–306*).—An account of the treatment of milk fever by iodid of potash and of the effect of spaying on the milk production of cows.

Abortion of cattle (*Vet. Jour., 49 (1899), No. 292, pp. 231–236*).—A general account of the different forms of this disease.

The value of separation and disinfection in combating abortion, J. SPEIR (*Jour. British Dairy Farmers' Assoc., 14 (1899), No. 3, pp. 228–230*).—The incubation period for this affection was found to be not less than from 40 to 42 days.

Protective inoculation against pleuro-pneumonia in Magdeburg, LEISTIKOW (*Arch. Wiss. u. Prakt. Thierh., 25 (1899) No. 6, pp. 443–450*).—Recommends the killing or protective inoculation of all cattle of infested herds.

A study of Bilharzia crassa in Sicily, P. BARBAGALLO (*Gior. R. Soc. Accad. Vet. Ital., 48 (1899), No. 37, pp. 865–873*).—A study of the parasitic life of this worm in cattle and sheep.

Caseous broncho pneumonia of sheep caused by the bacillus of Nocard-Preisz, F. SIVORI (*Rec. Med. Vet., Paris, 8. ser., 6 (1899), No. 20, pp. 657–671*).—In this paper the author makes a report on a disease among sheep in the Argentine Republic. The disease has been mistaken for tuberculosis and has also been called pseudotuberculosis. A large number of autopsies were made, on which the description of the pathological anatomy of the disease is based. The pathogenic organism was cultivated on several nutrient media, and experimental inoculations were performed on guinea pigs, rabbits, pigeons, white mice, goats, dogs, and sheep. When the culture is not especially virulent, the subcutaneous inoculation of the organism in sheep produces a large abcess. Intraperitoneal inoculation in the sheep causes death within a short time.

Epilepsy and Eclampsia, A. TAPKEN (*Deut. Tierärztl. Wchnschr., 7 (1899), No. 40, pp. 353–356*).—A study of this disease in horses, cattle, and hogs.

Observations on hog cholera and swine plague, G. GEROSA and G. BILLITZ (*Milch Ztg., 28 (1899), No. 30, pp. 465–468*).—Blood serum of experimental animals had neither preventive nor curative action.

Protective inoculations against hog cholera according to Lorenz and with Susserin, H. JOST (*Berlin. Tierärtztl. Wchnschr., 1899, No. 41, pp. 493–495*).—In a considerable number of experiments Susserin proved a valuable curative reagent for hog cholera.

The cure of hog cholera with intravenous injections of corrosive sublimate V. COLUCCI (*Gior. R. Soc. Acad. Vet. Ital., 48 (1899), No. 42, pp. 889, 890*).

Comparative investigation of the bacteria of hog cholera and swine plague, BÖDER (*Arb. K. Gesundheitsamte, 15 (1899), No. 3, pp. 373–386*).—The author claims that the organism of these two diseases can be distinguished by their unequal power of motion, the formation of cilia, their growth on agar and bouillon media, the formation of indol, and their zymogenic power. It is not thought probable that there are four related hog diseases, as some authors have maintained, but the two mentioned above are said to be easily differentiated.

Measures to be taken against the epizootic diseases of the pig, E. LECLAINCHE (*Jour. Comp. Path. and Ther., 12 (1899), No. 3, pp. 206-216*).—From a study of the great epizootics of swine fever it is concluded that not one arose by an extension of an old center of infection, but that all came by importation of fresh infection. The prevention of the disease lies, therefore, in the author's opinion, within the powers of the sanitary police officers.

Parasites in the stomach of the hog, S. VON RATZ (*Ztschr. Tiermed., 3 (1899), No. 4-5, pp. 322-329*).—Discusses *Simondsia paradoxa*, *Spiroptera strongylina*, and *Gnathostoma hispidum*.

Cerebro-spinal meningitis of the horse, CADÉAC (*Jour. Med. Vet. et Zootech., 5. ser., 3 (1899), pp. 523-526*).—A study of the symptoms of this disease.

Absorption of virus by the conjunctiva, V. GALTIER (*Jour. Med. Vet. et Zootech., 5. ser., 3 (1899), pp. 513-519*).—A report on a series of experiments in which it was shown that glanders could be transmitted by contact of the virulent matter with the conjunctiva without any pathological conditions arising in the conjunctiva.

The diseases of poultry, D. E. SALMON (*Washington, D. C.: G. E. Howard, 1899, pp. 248, figs. 71*) —A general treatise on the subject, arranged under the following chapters: Introduction; diseases of the organs of respiration; diseases of the organs of digestion; diseases of the peritoneum, liver, and spleen; diseases of the organs of urination and reproduction; diseases of the brain; diseases of the heart and blood vessels; parasites and diseases of the skin; diseases of the feet and legs; infectious diseases having a tendency to affect more than one set of organs; and injurious habits and vices.

Diseases of poultry, A. T. PETERS (*Nebraska State Bd. Agr. Rpt. 1898, pp. 233-237*).—A report of experiments in the destruction of fleas on poultry, in the use of the antitoxin treatment for roup, and in vaccination against fowl cholera.

Serum inoculation against fowl cholera, H. PRASSE (*Berlin. Tierärztl. Wchnschr., 1899, No. 45, pp. 542, 543*).—Experiments conducted upon 3 geese, 40 ducks, and 39 chickens showed that perfect immunity could be obtained by the use of serum.

Diphtheria of fowls, A. KLAVIKTER (*Schleswig-Holstein. Bl. Geflügelzucht, 21 (1899), No. 10, pp. 100-103*).—A study of the methods of infection and of means for preventing this disease.

Intracerebral inoculation of rabies virus, E. LECLAINCHE and C. MOREL (*Rev. Vet. Toulouse, 24 (1899), No. 10, pp. 593-598*).—By performing this operation in series, the virulence of the virus was increased, the incubation period being reduced from 16 to 9 days.

The germicide power and poisonousness of the three isomeric cresols and phenol, H. HAMMERL (*Hyg. Rundschau, 9 (1899), No. 20, pp. 1017-1028*).—Paracresol is shown to be equally as good as orthocresol for disinfecting, but more poisonous. Phenol is less poisonous than either, but is also less powerful as a disinfectant.

STATISTICS—MISCELLANEOUS.

Eleventh Annual Report of Alabama Station, 1898 (*Alabama Sta. Rpt. 1898, pp. 38*).—This includes the organization list of the station; financial statement for the fiscal year ended June 30, 1898; summary of the bulletins issued during the year; list of the subjects treated in the 100 bulletins issued since the organization of the station in 1888; list of exchanges; and departmental reports reviewing the work of the station along the different lines. The report of the associate chemist contains notes on methods employed at the station in investigations to determine the available plant food in soils, water requirements of the cotton plant, sources of nitrogen in leguminous plants, and the available phosphoric acid in phosphate.

Eleventh Annual Report of West Virginia Station, 1898 (*West Virginia Sta. Rpt. 1898, pp. 48, pl. 1*).—In addition to the organization list of the station and a financial statement for the fiscal year ended June 30, 1898, this contains a general review of the work of the station by the director, and more detailed reports by the chemist, entomologist, and horticulturist, enumerating the different lines of work and giving notes on the progress made during the year.

Crop circular for October, 1899, J. HYDE (*U. S. Dept. Agr., Division of Statistics Crop Circ., Oct., pp. 4*).—This contains notes on the condition of the principal crops in the United States and foreign countries, estimates of the world's wheat crop of 1899, and a table giving the average yield per acre, average quality, and average condition of crops by States and Territories, October 1, 1899.

Bulletin on the state of the crops in the Province of Quebec in July, 1899 (*Prov. Quebec, Dept. Agr., 1899, pp. 13*).—Summarized statistical data, showing the condition of the more usual farm crops with comments, and notes from correspondents.

Crops and live stock in Ontario (*Ontario Bureau Ind. Bul. 64, pp. 12*).—This bulletin gives the precipitation and temperature from November, 1898, to April, 1899, and a summary of reports on the condition of crops and live stock in the Province on May 1, 1899, with statistics on the agricultural products of Manitoba for 1897 and 1898.

The world's grain crops in 1899, J. HYDE (*U. S. Dept. Agr., Division of Statistics Circ. 11, pp. 8*).—English, French, and Hungarian estimates of the world's wheat crop of 1899 are given and discussed in connection with estimates of the Department. The estimates of the Hungarian ministry of agriculture of the total production of rye, barley, oats, and corn are also given.

The Brazos River (Texas) flood of June-July, 1899, and its effects upon the agriculture of the submerged region, E. S. HOLMES, Jr. (*U. S. Dept. Agr., Division of Statistics Circ. 10, pp. 8*).—In connection with a general account of the flood and of the agriculture of the flooded district estimates are given of the damage to property. The area covered by the flood contained a population of about 100,000. The region included 8,100 farms with an area of 1,383,350 acres and a total valuation, including farm implements, live stock, etc., of $23,445,555. The estimated total loss to farm property and crops amounted to $7,412,583.

Suggestions on farm accounts, C. D. SMITH (*Michigan Sta. Spec. Bul. 9, pp. 12*).—Practical method of keeping farm accounts are described and illustrative examples given.

Eighteenth Congress of German Wine Growers at Würzburg, September 16-20, 1899 (*Chem. Ztg., 23 (1899), No. 78, pp. 818-820*).—The papers dealt largely with methods of combating insects and fungus diseases.

NOTES.

Kansas Station.—At a recent meeting of the board of regents the management of the station was placed in the hands of a station council, composed of the president of the college, as chairman, and the heads of the various departments in the station. J. T. Willard was elected director, the office being charged with the executive duties, but not with the planning or supervision of work. The council is to hold regular monthly meetings. It was decided to lease suitable land for continuing experiments with the sand plum with a view to its improvement. A. T. Kinsley, B. S., has been appointed assistant in the veterinary department.

Oklahoma College and Station.—J. G. Kerr, B. S., a graduate of the Texas Agricultural College, has been appointed assistant in agriculture in the college and station.

Rhode Island Station.—George M. Tucker, formerly a regular assistant in agriculture and since his return from study in Europe a volunteer assistant at the station, has become general manager of a coffee and rubber plantation in the state of Oajaca, in Mexico, some 200 miles from Vera Cruz. The plantation is operated by Rhode Island capitalists.

Virginia College and Station.—The administration building was burned February 1. The building contained many valuable college and station records, and the station library and files of publications, all of which were lost. W. B. Alwood has been given a year's leave of absence for European travel and study. He plans to visit many of the agricultural institutions of England, France, and Germany, and will pay especial attention to recent progress in fermentation as applied to the manufacture of vinegar and other fermented products from cider. John F. Ryan, of Arcola; B. B. Brockenbrough, of Tappahannock; W. Wyndham Robertson, of Saltville, and J. S. Musgrave, of Pinopolis, have been appointed members of the board of visitors, to serve for four years, in place of W. B. Price, S. H. Graves, J. M. Barton, and H. L. Maynard, whose terms expired December 31, 1899.

West Virginia Station.—T. F. Watson, assistant chemist, died January 14, after a severe illness with typhoid fever and pneumonia.

Post-Graduate Study at Washington.—The committee of the Association of American Agricultural Colleges and Experiment Stations on post-graduate study at Washington has brought the matter definitely before the regents of the Smithsonian Institution and proposed a tentative plan for an office of post-graduate study in the Smithsonian Institution. The matter has been considered by a special committee of the board of regents, consisting of ex-Senator Henderson, Pres. W. L. Wilson, Prof. Alexander Graham Bell, Pres. J. B. Angell, and Representative Hitt. This committee has prepared a report which was presented at a recent meeting of the board of regents. The concluding lines of this report are as follows:

"The committee does not hesitate to express its warm and decided sympathy with the general purpose of the movement thus made by the associated colleges. The object sought commends itself to us all, and the zeal and ability with which it has been pressed upon our consideration by the very able and distinguished educators and scientists connected with these colleges furnish ample assurance that the consummation of the great and leading object sought by them is only a question of time. The material already collected in the bureaus and departments of the Government furnishes a rich mine of educational wealth that will not be permitted to remain forever undeveloped. This material is now being constantly enriched by the most valuable additions to its present enormous wealth. Already it has invited to the national capital many distinguished scientists, anxious to avail themselves of the superior advantages thus offered for investigation and research.

"Your committee, however, is painfully impressed with the fact that the powers of the Smithsonian Institution as at present organized are scarcely broad enough to embrace the work proposed.. And the committee is equally impressed with the fact that even with enlarged authority its present financial condition would absolutely prevent anything like efficient and creditable performance of the work contemplated.

"It is well known to the members of this board that a great wealth of material—material which would be of immense utility in the successful accomplishment of the purposes indicated by the associated colleges—lies buried in the crypts and cellars of the National Museum.

"If our institution is unable for want of room, as it undoubtedly is, even to place this valuable material on exhibition for the public eye, and as little to arrange it for scientific uses, the problem of providing halls for lectures and meeting the necessary expenditures incident to the work proposed becomes serious and formidable in the extreme. Your committee is not prepared to make definite recommendations to the board for its final or ultimate action. That which is clearly inexpedient to-day may become not only expedient but eminently desirable to-morrow."

No final action was taken by the regents, and the matter will be further considered at a special meeting.

The committee of the Association of American Agricultural Colleges and Experiment Stations and a similar committee from the National Educational Association will hold a joint meeting in Chicago the latter part of February, with reference to securing the cooperation of the two associations in arranging for post-graduate study at Washington.

INTERNATIONAL BOTANICAL CONGRESS.—According to the Journal of Botany, an international botanical congress will be held in Paris in connection with the universal exposition from the 1st to the 10th of October, 1900. An official commission has been organized, among the members of which are M. Prillieux, president, and MM. Guerin and Lutz, secretaries. Among the questions approved by the commission and which will be presented before the congress are: Monograph studies; a discussion of species, hybrids, and crosses; unification of micrometrical measures; and the influence of the nature of soil and host plants on development of fungi. The rules for the congress are given, and it is desired that the commission should receive official notice as soon as possible of any botanists expecting to take part in the congress.

MISCELLANEOUS.—The inaugural lecture of the department of agriculture of the University of Cambridge, England, delivered by Professor Somerville, has been published by the University Press. The subject of the address is, Some aspects of the bearings of education and science on practical agriculture. It points out some of the relations of science to agriculture and the advantages of agricultural education. It will be remembered that the chair of agriculture in the University of Cambridge was endowed for a period of 10 years. It is hoped that it will be the means of increasing the interest in agricultural education in England and the recognition by farmers of the assistance which science and agricultural education can give to agriculture.

PERSONAL MENTION.—Prof. F. Wohltman, of Bonn, who has made quite a study of tropical agriculture in Africa, has again gone to that country, at the request of the Government, to continue his studies in the Cameroon district.

Dr. Max Lehmann, formerly assistant in the experiment station at Möckern, has become agricultural chemist at the Imperial Central Experiment Station at Tokyo.

Prof. Max Barth, director of the experiment station at Colmar, Germany, died recently in his forty-fourth year. His scientific investigations related principally to the culture of grapes and wine making.

Dr. C. Correns has been chosen associate professor of botany at Tubingen.

Dr. J. B. De Toni has become professor of botany and director of the Botanical Garden of the University of Camerino, succeeding Prof. A. N. Berlese, who has been chosen professor of natural science of the Royal Lyceum.

EXPERIMENT STATION RECORD.

VOL. XI. No. 8.

The observations noted in the present number in regard to the presence of leucocytes, or white blood corpuscles, in milk are of interest from the fact that the literature contains very little reference to the occurrence of these bodies in milk, and furthermore from the theory which the author advances regarding their peptonizing action.

Leucocytes are held to be a normal constituent of cows' milk, and are said to be more abundant in cream. These observations are supported by the investigations of Eastes, noted in the preceding number. The latter found that normal milk always contains leucocytes, the number being especially marked during the first week of lactation, when they are accompanied by colostrum corpuscles, and then decreasing until there are only a few. They adhere to the fat globules, which often coalesce, forming conglomerations, and hence they are present in largest numbers in the cream.

The presence of leucocytes in milk is not difficult to account for, since they are always present in the blood, and are formed in unusually large numbers in case of certain diseases or injuries, and accumulate in the region of the trouble. They are able to pass the walls of blood vessels and cells, and in case of any lesion of the mammary gland or udder they would be quite likely to be present and to gain access to the milk.

The paper by Barthel in the present issue attributes to the leucocytes of milk, or an enzym secreted by them, the peptonizing action ascribed by Babcock and Russell, of the Wisconsin Station, to the unorganized milk ferment, galactase. The evidence of this action of the leucocytes does not appear to be supported by any considerable amount of experimental data. It rests mainly on the similarity between galactase and the leucocytes in giving the Storch test with hydrogen peroxid, and in their alleged behavior toward certain anæsthetics. But the white blood corpuscles found in clotted blood have only a slight digestive action, and the work thus far done in introducing blood into sterilized milk fails to show that any marked digestive effect is brought about thereby. Galactase, on the contrary, has been shown to be an active agent in this respect, having a pronounced digestive action on the insoluble proteids of milk, in the absence of bacteria, and forming characteristic decomposition products which distinguish it from trypsin or any unorganized ferment known. The Storch test has not been relied upon as conclusive evidence of the presence of galactase, but only as a convenient test for indicating its presence.

The suggestion that the changes attributed to galactase are traceable directly or indirectly to the leucocytes appears to have very little of the element of probability in it, in view of the convincing work which has been done on galactase; but since leucocytes appear to be a constituent of milk and the action of these bodies is not definitely known, an interesting line of investigation is opened up, which may possibly throw some light on the nature or action of other milk enzyms.

Dairy bacteriologists seem gradually to be conceding the importance of the action of milk enzyms in explaining the proteolytic changes in cheese during ripening. The contention that the process is due entirely to the action of bacteria or other micro-organisms has simmered down to a controversy in which one point after another has been relegated to the background. Little or no new material is being published which affords any additional support to the theory that bacteria are necessary, or that unaided they are capable of inducing the characteristic ripening changes. Lactic-acid bacteria, to which the changes were formerly attributed, are no longer held to play more than an incidental rôle in the process, and it has even been admitted by a most ardent advocate of the bacterial theory that galactase may possibly prepare the casein for the action of the lactic acid bacteria, which then complete the decomposition. In his latest communication Freudenreich goes so far as to say that "for the present we are unable to determine how much of the solvent action on the casein is due to the action of the lactic-acid ferments and how much to the action of the natural milk enzym," and the doubt expressed as to the part played by lactic-acid organisms is enforced by his latest experiments. Others have argued that the lactic-acid bacteria take no real part in the ripening process further than to give it the proper direction, by the conditions which they bring about, and that the true ripening changes and the production of flavor and odor are due to a variety of other forms.

It was quite natural that at the outset the presence of large numbers of bacteria in ripening cheese should suggest their causal relation and set investigation in that direction; but the demonstration that cheese can be made and cured under conditions which preclude the growth of bacteria would seem to demand more satisfactory and convincing evidence than has yet been adduced that their presence is not merely an accident rather than a necessity.

In extent and thoroughness the work of Babcock and Russell surpasses that of any other investigators of the subject, and it has been notable for its broad-mindedness and freedom from bias. It has been a scientific search for the truth, in which the current theories have been given full and unprejudiced consideration. The new theories advanced by them have been founded on systematic investigation, and have been submitted to critical test before giving them to the public. These facts must strengthen conviction in the accuracy of the general theory that enzyms which are inherent in milk play the principal rôle in proteolytic changes in cheese ripening, as reaffirmed in their latest contribution.

Until recently their work was confined to hard cheese (Cheddar), but an extension of their studies to cottage cheese indicates very strongly that here too the digestion of the casein is due chiefly to galactase in the milk, and that bacteria and molds exercise at most very little effect. In fact, the indications are that bacteria of the lactic acid group have no appreciable effect on casein digestion.

Under normal conditions of cheese making a variety of micro-organisms are present, and it is quite probable that a number of different forms take part in the ripening process, the galactase peptonizing the casein, and certain bacteria or molds producing decomposition products in the cheese which give it the characteristic taste, odor, and general appearance. The degree of activity of these different forms depends considerably upon the proportions in which they are present and the conditions which they bring about in the cheese, inhibiting certain forms and rendering it a more advantageous medium for the growth of others. Consequently a knowledge of the essential or desirable ferments and micro-organisms and the best conditions for their growth will place the curing of cheese on a more intelligent and rational basis.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The determination of pentosan-free crude fiber according to J. König, O. KELLNER, F. HERRING, and O. ZAHN (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 10, pp. 784–786*).—In connection with a series of feeding experiments the authors studied the accuracy of König's method (treatment in an autoclave with sulphuric acid and glycerin; E. S. R., 10, p. 411). Duplicate determinations by the method were found to agree about as closely as by the Weende method. The amounts of pentosans and nitrogen left in the crude fiber by the König and the Weende methods were compared on a number of samples of steer dung—material which from its nature contains larger quantities of difficultly soluble pentosans and nitrogenous substances than most feeding stuffs. The ash-free and water-free fiber by the König method contained from 2.38 to 3.34 per cent of pentosans, while that obtained by the Weende method contained from 16.08 to 19.81 per cent. The percentage of nitrogen was slightly higher in the crude fiber prepared by the König method.

The results obtained by the König method on straw and a number of samples of steer dung were compared with those obtained by the Weende method, correcting the latter figures for the pentosans found in the crude fiber. The results obtained with the two methods in this way were nearly the same in the case of straws, but differed as much as 2 per cent in the case of the dungs, there being no regularity as to which method gave the higher result.

The authors consider the König method an improvement over the laborious Weende method. Used in connection with the Tollens method for determining pentosans, the pentosan-free and nitrogen-free fiber can be calculated more accurately. The method is recommended for use in digestion and metabolism experiments as being more accurate, rapid, and easier carried out than the Weende method, and as effecting a sharper separation of constituents.

On the application of the law of equilibrium to the formation of oceanic salt beds with special reference to the Stassfurt salt deposits, J. H. VAN'T HOFF and W. MEYERHOFFER (*Ztschr. Physikal. Chem., 27 (1898), pp. 75–93, figs. 6; 30 (1899), pp. 64–88, figs. 5; abs. in*

J[illegible]em. Soc. [*London*], *78* (*1900*), *No. 446*, *II*, *p. 12*).—These two artic[illegible]e the results of a study of the statics of hydrated magnesium c[illegible]and carnallite, with a brief description of the apparatus and m[illegible]s used. This is the beginning of a systematic study of the s[illegible] of the various salts found in sea water, which is considered n[illegible]ry to a clear understanding of the causes producing the Stassfu[illegible]d other salt deposits.

D[illegible]ination of nitrogen in saltpeter, M. SCHMÖGER (*Chem. Ztg.*, *23* (*1899*), *No.* [illegible] *829*).—The author briefly reports comparative tests of the Raab-Böttcher, Ulsc[illegible]varda, and Kjeldahl-Förster methods. All gave results somewhat too low, the g[illegible]st error occurring with the Raab-Böttcher method, the least with the Deva[illegible] method (E. S. R., 9, p. 723). The latter (reduction in alkaline solution with alum[illegible]um-copper-zinc alloy) is considered the best and quickest of the methods.

O[illegible]he determination of nitric acid in water, M. HÖNIG (*Festschrift Tech. Hochsch[illegible] Brünn, Oct., 1899; abs. in Chem. Centbl., 1899, II, No. 24, p. 1032*).

[illegible] the determination of sulphuric acid in the presence of iron, G. WYROUBOFF (*[illegible]l. Soc. Chim. Paris, 3. ser., 21* (*1899*), *No. 24, pp. 1046–1049*).

On the determination of the iodin value, J. LEWKOWITSCH (*Analyst, 24* (*1899*), *Oct., pp. 257-259*).—A statement of some results obtained in comparing Wijs' modification of Hübl's process, using a solution of iodin chlorid in glacial acetic acid, with the original method. The results lead to the conclusion that the original method is perfectly reliable.—G. W. SHAW.

The detection of salicylic acid and benzoic acid in milk, G. BRENSTEDT (*Arch. Pharm., 237* (*1899*), *pp. 170–172; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 2* (*1899*), *No. 11, p. 866*).

Method for detecting and determining formaldehyde in free state and in its combination, G. H. A. CLOWES and B. TOLLENS (*Ber. Deut. Chem. Gesell., 32* (*1899*), *No. 15, pp. 2841–2848; abs. in Chem. Ztg., 23* (*1899*), *No. 96, Repert., p. 350*).—The substance to be tested for formaldehyde or methylen is heated for 2 hours on a water bath at 70 to 80° C. with a mixture of 15 cc. hydrochloric acid (sp. gr. 1.19), 15 cc. of water, and an excess of phloroglucin. To the filtrate a little concentrated sulphuric acid is added and the solution heated again. If the phloroglucid is precipitated again it is evident that the hydrochloric acid mixture was not sufficient to decompose the methylen derivatives and the experiment must be repeated, heating the substance with 5 cc. of water and a mixture of 10 to 20 cc. of concentrated sulphuric acid, 10 cc. of water, and phloroglucin.

Detection of nicotin, J. SCHINDELMEISER (*Pharm. Centralhalle, 1899, p. 703; abs. in Chem. Ztg., 23* (*1899*), *No. 98, Repert., p. 361*).—Formaldehyde and concentrated nitric acid gives a rose color to dark red with nicotin.

The analysis of golden sirup, R. BODMER, N. LEONARD, and H. M. SMITH (*Analyst, 24* (*1899*), *Oct., pp. 253–257*).—The writers set forth their method of analysis, and present analyses of 26 samples of "golden sirup," 21 of which are made largely from glucose.—G. W. SHAW.

How to detect adulterants in milk, LEFFMANN and BEAM (*Dairy, 11* (*1899*), *No.* [illegible], *p. 372*).—Qualitative tests are given for the detection of water, coloring matters, antiseptics, and other substances added to milk.

Simplifying the phenylhydrazin test for sugar, A. NEUMANN (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. pt. 2, pp. 549–552, fig. 1*).

Egg albumin, T. B OSBORNE (*Connecticut State Sta. Rpt. 1898, pp. 317–325*).—This article has been abstracted from another source (E. S. R., 11, p. 309).

Changes in the physical state of proteid bodies (*Arch. Physiol.* [*Pflüger*], *78* (*1899*), *No. 7–8, pp. 315–345, figs. 8*).—A study of a number of proteids by methods of physical chemistry

Studies concerning nucleones, R. T. KRUGER (*Ztschr. Physiol. Chem., 28 (1899), No. 5–6, pp. 530–534*).—The author reports experiments on the nucleon of muscular tissue and milk, with special reference to solubility in salt solutions.

Serum globulin soluble in water, E. MARCUS (*Ztschr. Physiol. Chem., 28 (1899), No. 5–6, pp. 559–575*).—A number of experiments are reported.

Studies on the properties of glutin (gelatin), C. T. MÖRNER (*Ztschr. Physiol. Chem., 28 (1899), No. 5–6, pp. 470–523*).—A large amount of experimental research is reported. The article also contains a bibliography of the subject.

Methylen-glucose, a new glucoside from glucose, formaldehyde and hydrochloric acid, B. TOLLENS (*Ber. Deut. Chem. Gesell., 32 (1899), No. 14, p. 2585; abs. in Chem. Ztg., 23 (1899), No. 88, Repert., p. 311*).

Investigation of arabic acid from sugar beets, VOTOČEK and SEBOR (*Böhm. Ztschr. Zuckerind., 24 (1899), p. 1; abs. in Chem. Ztg., 23 (1899), No. 88, Repert., p. 311*).

The saccharification of starch, POTTEVIN (*Ann. Inst. Pasteur, 13 (1899), No. 8, p. 665; abs. in Chem. Ztg., 23 (1899), No. 84, Repert., p. 302*).—A chemical study of the process.

Inorganic ferments: Platinum catalysis and the chemical dynamics of hydrogen peroxid, G. BREDIG and R. MÜLLER VON BERNECK (*Ztschr. Physikal. Chem., 31 (1899), pp. 258–353, figs. 3*).—The analogy of certain reactions induced by inorganic substances to true fermentation is pointed out.

A method for collecting and analyzing intestinal gases and those due to fermentation, N. ZUNST (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, No. 5–6, pp. 579–586, fig. 1*).—The author describes in detail an apparatus for the measurement and analysis of these gases.

Report of the Chemical Control Station in Christiania, Norway, 1898, F. H. WERENSKIOLD (*Aarsber. Offent. Foranst. Landbr. Fremme, 1898, pp. 106–151*).

BOTANY.

The flowering and pollination of Indian corn, W. R. LAZENBY (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 123–129*).—The author reports observations on the flowering of corn, the studies having been made on a number of varieties for a considerable time. Among the varieties under observation were 5 of dent, 4 of flint, and 4 of sweet corn. The number of flowers upon a stalk of corn is found to vary widely in the same variety as well as to show marked differences. An estimate was made of the average number of pistillate and staminate flowers of different kinds of corn. The ratio of pistillate to staminate flowers in dent corn was 1:6; in flint corn, 1:7, and in sweet corn, 1:3.5. The author investigated the approximate number of pollen grains and ovules in the 3 different classes of corn and gives the ratio in round numbers. From the figures given there is shown to be a great excess of pollen. The relation between the time of shedding pollen and the appearance of silk is stated, in which it is shown that in a large majority of cases the pollen had begun to be shed before the silk appeared. It is stated that in several cases where pistillate flowers were found associated with the staminate ones that the pistillate flowers in every case developed first. As a rule, however, the discharge of pollen is said to begin from 2 to 5 days before the silk appears and the length of time in which the pollen is discharged varies from 5 to 10 days, dependent upon the variety, temperature, sunshine, and dryness of the weather.

From measurements of the rate of growth of a number of plants, it is stated that a plat of Livingston dent was in full blossom 60 days from the date of planting and the stalks averaged a little over 8 ft. in height, making the rate of growth of these plants a little in excess of 1.5 in. per day from the date of planting.

The author's conclusions are that many if not most of the common varieties of Indian corn require cross pollination, being partially or wholly incapable of producing a fertile ear when limited to pollen from the same stalk. The principal reason for this is that the pollen matures before the stigmas are receptive. Under favorable circumstances, there is a great excess of pollen produced and corn is usually well pollinated in fields of considerable size, owing to the duration of the period of flowering. Imperfect ears of corn are not due to imperfect pollination alone but to imperfect ovules as well.

Fertilization of the muskmelon, F. W. Rane (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 150, 151*).—The muskmelon is generally reported as being either monœcious or diœcious but the author reports that in examining what were considered pistillate flowers well developed stamens were found. On closer examination there were found not only well-developed stamens but the stamens were prolific with pollen. The same varieties were later examined out of doors and found not to vary in the least. Of a number of varieties examined the flowers of 84 proved to be perfect and only 11 imperfect or monœcious. Many flowers were covered just previous to opening and then pollinated with their own pollen with the result that many specimens were developed which were comparatively self-fertile.

Influence of light on the formation of active proteid materials in plants, W. Palladin (*Rev. Gén. Bot., 11 (1899), No. 123, pp. 81–105; also briefly noted in Compt. Rend. Acad. Sci. Paris, 127 (1899), No. 6, pp. 377–379*).—In a previous work (E. S. R., 8, p. 843) the author has shown the correlation existing between the respiratory energy of plants and the amount of active nitrogenous compounds which are formed. The cell products are classified by the author into dead products, of which the cell membrane, starch, crystals of calcium oxid, aleuron grains, crystalloids, and proteids dissolved in cell sap are the principal ones, and living or active products, such as protoplasm, nucleus, chlorophyll grains, and leucites. Some of the conditions under which the latter class of products are formed are shown in the present paper

The experiments, which are described in considerable detail, were mostly made upon etiolated bean seedlings grown in 5 and 10 per cent solutions of sugar. After about 6 days, plants which had been kept in darkness were compared with those grown in the light for the same time. It was found that the leaves assimilated in the light three times as much saccharose as in darkness. In the presence of saccharose the synthesis of proteid material takes place much more energetically in the light than in darkness. For 100 gm. of fresh leaves the nitrogen in the proteid substances increased 248 mg. in the light as compared with 97 mg. in darkness. The regeneration of proteids takes place much more actively in the blue portion of the spectrum than in the yellow. The presence of an abundant carbohydrate reserve and the action of light are indispensable to the normal formation of nitrogenous substances in living leaves.

The respiration of the plants in light and darkness was compared. It was shown that when cultivated in sugar solutions, leaves which are exposed to the light give off more than twice as much carbon dioxid as those cultivated under the same conditions but kept in the dark.

The author states that there is a correlation between the carbon dioxid given off and the nitrogen content of the proteids, and in each series of experiments when comparisons were made between leaves exposed to the light and those kept in darkness, the proportion of carbon dioxid to nitrogen was constant.

Effect of electric light upon the tissues of leaves, W. W. ROWLEE (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 50–58, pls. 2*).—In connection with studies of the general effect of electric light upon growth and maturation, investigations were undertaken to determine what, if any, effect electric light has upon the tissues of plants. When the arc light is used it has been known for sometime that some plants are seriously injured while others are little or not at all affected. Experiments were conducted by the author to ascertain the change in structure of the tissues of plants susceptible to the influence of electric light, and the difference in leaf structure that enables one group of plants to withstand the electric light while another in the same condition would be seriously injured or totally destroyed.

Four species of plants were selected for special study, 2 of which showed an immediate injury under the light, and 2 others which were apparently not at all affected. The ones selected to represent the plants susceptible to light were heliotrope and coleus; and those not susceptible, *Ficus elastica* and a species of Coronilla. The plants were divided into 2 groups, one of which was kept under conditions of normal light and darkness while the other was placed about 1 meter from a naked arc light in such a position as to receive the direct rays of light. The leaves were examined before and after exposure to the light and the differences noted. The tissues of the leaves which were not perceptibly affected by the light were not altogether uniform, and were developed in such a way as to retard too rapid transpiration. In the case of the leaves affected by the light their structure was quite uniform and the cell walls comparatively thin. The immediate effect of the light upon these leaves is shown by the upper epidermis, the cells of which completely collapse. After 8 hours subjection to an unscreened arc light the epidermis on both heliotrope and coleus leaves had collapsed and the epidermal hairs exhibited a tendency in that direction. This injurious effect may be prevented by the interposition of a screen of ordinary glass. The author thinks the effect is produced by the destruction of the protoplasm itself and not by any increased activity in transpiration.

Plant relations; A first book of botany, J. M. COULTER (*New York: D. Appleton & Co., 1899, pp. VII + 264, figs. 206*).

Recent additions to systematic agrostology, F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Circ. 15, pp. 10, figs. 5*).—This circular is supplemental to the translated edition of Hackel's "True Grasses," which appeared in 1890. Recent important additions to the literature and descriptions of new genera have been cited in Hackel's supplement to the above work The recently-described genera and important changes in the nomenclature not published in the supplement warrant their presentation at this time for the use of American students of grasses.

New species of North American grasses, F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Cir. 16, pp. 6, figs. 2*).—The following new species of grasses are described by the author: *Puccinellia simplex, Poa curtifolia,* and *Dactyloctenium australiense;* and *Panicum orinum, P. inflatum, P. thurowii,* and *P. octonodum* are described by the author, in conjunction with J. G. Smith. A number of new combinations of names are also given.

Some ecological notes on Iowa grasses, L. H. PAMMEL (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 204–211*).—The author gives the distribution of Iowa grasses as related to ecological factors from which it appears that there is but a single species of grass which is adapted to salt marshes or alkali soils. Among the Xerophytic grasses which are adapted to growth in rather dry soils 17 species are enumerated. A striking peculiarity of all the Xerophytic grasses is that they grow in bunches. The leaves are so constructed that transpiration is reduced to a minimum.

Of the third group, termed Mesophytic grasses, 20 species are enumerated which are adapted to forest and prairie regions. The Hydrophytic grasses, or those which are unable to withstand the injurious effect of dry soil and weather, are represented by 11 species. A final class, which the author has termed Agragrian, embraces those species which are not limited to any peculiar condition of soil or climate, but have adapted themselves to a variety of conditions. Twelve such species are enumerated, this list including many of the more common weed-like grasses.

A synoptic conspectus of the native and garden species of Aconitum of North America, K. C. DAVIS (*Minnesota Bot. Studies, 2. ser., 1899, pt. 3, pp. 345–352*).

A synoptic conspectus of the native and garden Aquilegias of North America, K. C. DAVIS (*Minnesota Bot. Studies, 2. ser., 1899, pt. 3, pp. 331–343*).

The genus Psalliota, C. G. LLOYD (*Mycological Notes, 1899, No. 4, pp. 25–30*).—The author describes a number of new species of this genus, and gives a synopsis and notes on the species recorded from this country. Psalliota has been adopted by the author as the name for the genus Agaricus.

Some new species of Aspergillus, C. WEHMER (*Bot. Centbl., 80 (1899), No. 12, pp. 449–461, fig. 1*).—*Aspergillus varians, A. minimus,* and *A. ostianus* are described and their relationships discussed.

Notes on the fertilization of flowers, W. M. MUNSON (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 176–183*) —Notes are given on some of the more salient points concerning the passage of the male nucleus from the pollen grain to the embryo sac, the idea being to bring together the available data for use in future work. Notes are given on the character of the pollen grain, on its germination, and the growth of the pollen tube, and on the method of entering the nucellus. Some of the secondary effects of pollination are pointed out and statements given relative to the amount of pollen required for fertilization.

On the functions of aerial roots, A. NABOKICH (*Bot. Centbl., 80 (1899), Nos. 9, pp. 331–340; 10, pp. 376–384; 11, pp. 423–432; 12, pp. 471–477; 13, pp. 503–510, pls. 2*).

The distribution of lithium in plants, E. TSCHERMAK (*Ztschr. Landw. Versuchw. Oesterr., 2 (1899), pp. 560–571; abs. in Chem. Ztg., 23 (1899), No. 102, Repert., p. 381*).

Aldehyde in green leaves, J. REINKE and E. BRAUNMÜLLER (*Ber. Deut. Bot. Gesell., 17 (1899), pp. 7–12; abs. in Jour. Roy. Micros. Soc. [London], 1899, pt. 5, p. 499*).—A number of series of experiments on different plants to determine the effect of light on the amount of aldehyde contained in green leaves is reported, in which the results secured were not uniform, but in general it is claimed that depriving plants of light caused a distinct diminution in the amount of aldehyde present. The authors conclude that aldehyde is probably not the first product of assimilation, but whatever the first product may be, it is in the majority of cases first condensed into sugar.

Cane sugar in plants, E. SCHULZE (*Ztschr. Phys. Chem., 27 (1899), pp. 267–291; abs. in Jour. Roy. Micros. Soc. [London], 1899, pt. 6, p. 612*).—The author reports the wide distribution of cane sugar in ripe seeds of plants, although in many cases it occurs in very small quantities. It has been observed in the seeds of a number of conifers. Cane sugar is considered of importance as a reserve material in the process of germination, but as it increases as growth proceeds it probably fulfills other uses. Accompanying cane sugar there are frequently present in large quantities other soluble sugars capable of inversion.

Concerning reserve protein, J. GRUSS (*Wchnschr. Brau., 16 (1899), No. 41, pp. 532–534, pl. 1*).

On the chemistry of chlorophylls, L. MARCHLEWSKI (*Jour. Prakt. Chem., n. ser., 60 (1899), pp. 91–96*).

The physiology of tuber formation, H. VÖCHTING (*Jahrb. Wis. Bot. [Pringsheim], 34 (1899), No. 1, pp. 1–148, pls. 5, figs. 9*).—The results of experiments and studies on the production of organs modified to perform vicarious functions are reported. The structure and physiology of tuber formation is given for normal and special conditions. The subjects of experiment embraced *Oxalis crassicaulis*, *Boussingaultia baselloides*, *Thladiantha dubia*, *Gloxinia speciosa*, *Raphanus sativus*, *Helianthus tuberosus*, *Sedum maximum*, *Apios tuberosa*, and several varieties of potatoes.

A case of atavism in the potato, S. RHODIN (*Tidskr. Landtmän, 20 (1899), No. 12, pp. 207–210*).

On the effect of acid gases on plants, WIELER (*Verhandl. Naturhist. Ver. Preuss. Rheinlande, 56 (1899), No. 1, pp. 44–49*).—The effect of fumes and vapors carrying acid gases as shown by studies of foliage and wood are given.

The toxic effect of ammonium salts, S. TAKABAYASHI (*Imp. Univ. Col. Agr. [Tokyo] Bul., vol. 3, No. 3, p. 265; abs. in Ann. Agron., 25 (1899), No. 6, p. 301*).

Electrolytic dissociation and its toxic effect, J. F. CLARK (*Jour. Phys. Chem., 3 (1899), pp. 263–317*).

The influence of inorganic salts on the conidia formation of Aspergillus niger, A. YASUDA (*Bot. Mag. [Tokyo], 13 (1899), No. 149, pp. 85–90*).

Formation of conidia in fungi, C. WERNER (*Die Bedingung der Conidien-bildung bei einigen Pilzen. Frankfort-on-the-Main, 1898, pp. 48, figs. 55; abs. in Jour. Roy. Micros. Soc. [London], 1899, No. 4, p. 420*).—The author distinguishes in *Nectria cinnabarina* three forms of conidia. The first, which he calls aquatic, may be abstricted in an irregular way from all the hyphæ. The second are aerial conidia formed on simple or branched erect conidiophores; and the last group, those formed on branched crowded hyphæ, have often a strong developed stroma, their form being always narrowly elliptical. The first kind are formed in fluid media, the second on a nutrient agar or gelatin, and the third are produced when the substratum is drier than the surrounding air. The formation of the conidia is found to decrease as the concentration of the medium is increased. In *Volutella ciliata* abundance of nutriment and low transpiration induces the formation of tufts of conidiophores, while if the nutriment is deficient and transpiration low, simple conidiophores are produced.

Nitragin and the nodules of leguminous plants, MARIA DAWSON (*Phil. Trans. Roy. Soc. London, ser. B, 192* (*1899*), *pp. 1–28, pl. 1*).—This is the complete paper, a résumé of which has already appeared (E. S. R., 11, p. 25). An extensive review of literature is given and the author's experiments are described in detail.

Experiments with Alinit, W. KRÜGER and W. SCHNEIDEWIND (*Landw. Jahrb.*, *28* (*1899*), *No. 3–4, pp. 579–591*).—Details are given of pot, bed, and field experiments with Alinit. No benefit whatever resulted from its use on sugar beets, potatoes, oats, or mustard, the crops experimented with.

Influence of organic material on the action of nitrifying organisms, S. WINOGRADSKY and V. OMÉLIANSKY (*Arch. Sci. Biol.* [*St. Petersburg*], *7* (*1899*), *No. 3, pp. 233–271*).

ZOOLOGY.

Results obtained by bacteriological methods of fighting susliks (Spermophilus rufescens) (*Selsk. Khoz. i Lyesov., 192* (*1899*), *Mar., pp. 583–618*).—In experiments conducted for the purpose of determining the value of different disease germs in destroying susliks, cultures were made of the germs of chicken cholera, mouse typhus of Löffler, mouse dysentery of Danisch, Merezkhovski's suslik bacillus, and the rat bacillus of Isachenko.

The method of infecting the susliks with cultures of various germs may be described as follows: Wheat was heated in water up to the boiling point, then removed and thoroughly dried in the sun. It was afterwards placed in sacks and kept until needed for use in the field. The wheat was infected with the pathogenic germs by soaking it, in the field, in vessels containing the cultures of the germs. As soon as the wheat was thoroughly saturated, it was used for infecting the burrows, a small quantity being placed in each burrow. During laboratory experiments with these disease germs upon susliks, it was found that the virulence of the bacilli could be increased to a considerable extent by passing cultures through the organism of susliks. The degree of virulence of cultures of chicken cholera when passed through the susliks was highest on the fifth and sixth days; of the Löffler bacillus, on the ninth day.

The bacilli of mouse typhus and mouse dysentery were found very effective in the destruction of susliks. The bouillon cultures of the pathogenic germs were prepared on the day previous to use. As soon as the wheat had been soaked in the culture, a tablespoonful of it was immediately placed in a burrow. Experiments in the field demonstrated that if no green herbage is to be found and if every burrow is infected, the bacilli of chicken cholera or mouse typhus may be relied upon for favorable results in destroying susliks. It was found, however, that when some burrows were infected and others left uninfected, the disease was not transmitted from the susliks of infected burrows to those of the uninfected burrows except to a limited extent.—P. FIREMAN.

The life history and means of combating the tobacco nematode (Heterodera radicicola) in Deli, J. VAN BREDA DE HAAN (*Meded. 'S Lands. Plantentuin, 1899, No. 35, pp. 68, pls. 3*).—In this article the author gives detailed descriptions of the egg, larval, and adult forms of a nematode which was found to be very injurious to tobacco in Deli. An account is given of the life history, habits, systematic position, and distribution of the nematode, and the internal and external appearance of the galls caused by the activity of the nematodes upon tobacco roots are described and figured.

The results of the author's work may be summarized as follows: The nematode which was found parasitic upon the roots of the tobacco plant is considered to be *Heterodera radicicola.* This nematode occurs upon many other plants, even in virgin forest land. When the nematode penetrates the roots of tobacco, a gall formation results, which modifies the structure of the roots, producing an increase of parenchyma cells and a number of so-called giant cells. The eggs are found inside of the gall tissue, and the young, after hatching in this situation, may eventually emerge from the galls and can live for some time outside. It is probable that Heterodera can also live saprophytically. The destruction of the root tissue hinders the normal development of the plants by preventing the proper amount of water in the parts of the plants above ground. As soon as the galls reach a certain age, they may split open and thus allow other organisms to enter and cause the premature death of the plants. Culture methods may be adopted which will prevent in a large degree the distribution of Heterodera. When the soil is once infested with these nematodes, it can be freed from them by the use of gasoline and other chemical substances.

Nature's foresters, E. H. FORBUSH (*Massachusetts State Bd. Agr. Rpt. 1898, pp. 279–294*).—This paper gives a popular account of the activity of the various birds, mammals, and insects in scattering the seeds and nuts of different forest trees as well as in destroying buds and branches of trees.

An observation on the feeding habits of the chipping sparrow, C. M. WEED (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 109–111*).—An abridged form of New Hampshire Station Bulletin 55 (E. S. R., 8, pp. 726, 727).

Animals injurious to sugar beets, W. HERZOG (*Monographie der Zuckerrübe. Hamburg: L. Voss, 1899, pp. 144–165*).—In his monograph of the sugar beet the author devotes one section to a discussion of the animal enemies of the sugar beet. Among nematodes the author gives consideration to *Heterodera schachtii, Dorylaimus condamnus, D. incertus,* and *D. makrodorus.* The nematodes are parasitized by several species of fungi.

Biological and economic notes are also given on numerous species of insects, centipedes, and earthworms.

An epizooty of Strongylus strigosus in rabbits in Scotland, F. V. THEOBALD (*Jour. Southeast. Agr. Col., Wye, 1899, No. 8, pp. 60–62*).—This nematode is reported as having caused the death of large numbers of rabbits by perforating the walls of the stomach.

Red cats and disease, R. HENRY (*Trans. and Proc. New Zealand Inst., 31 (1898), pp. 680–683*).—The raising of cats to assist in the extermination of rabbits gives some economic importance to these animals. During several disastrous outbreaks of distemper among cats it was observed that cats of a red color were almost entirely immune to the disease.

FERMENTATION—BACTERIOLOGY.

Alcoholic fermentation without yeast cells, E. BUCHNER and R. RAPP (*Ber. Deut. Chem. Gesell., 32 (1899), pp. 2086–2094; abs. in Jour. Roy. Micros. Soc. [London], 1899, pt. 6, pp. 622, 623*).—The authors' conclusions, based upon a large number of experiments, are quoted as follows:

(1) When yeast which has been well triturated with kieselguhr and quartz sand, is fractionally filtered under a pressure of 60 kg. per sq. cm., the liquid which runs through first is far less active than the later fractions, the most active portion being obtained by a second trituration and filtration without the addition of more water. From 1,200 gm. of yeast with the gradual addition of 65 cc. of water, 730 cc. of active extract may be obtained. When, however, the extract is filtered through biscuit porcelain, the first 20 cc. are much more active than any of the subsequent fractions.

(2) Fermentation takes place equally readily with solutions containing from 15 to 30 per cent of sugar; in such case toluene is added and the temperature kept at 23° C. When sugar is not present, very little fermentation takes place, the maximum amount of carbon dioxid evolved from 20 cc. of extract, after 40 hours, being 0.06 gm., and after 88 hours, 0.1 gm.

(3) Starch itself is not fermented by the extract, but "soluble starch" and dextrins of various origins are readily fermented.

(4) Glucose and fructose are fermented at practically the same rate, both by yeast extract and by fresh Munich bottom yeast. This conclusion is, however, not in accord with statements made by other authorities.

(5) The previous irregularities noticed on the addition of potassium arsenite to the yeast extract are probably to be explained by the proteids in the extract protecting the zymase from the action of the arsenite; as it has been found that the dilution of the extract with water, in the presence of 2 per cent of arsenite, practically stops fermentation, whereas dilution with blood serum or liquids rich in proteids, or even sugar solution, in the presence of the same amount of arsenite, retards the fermentation to a slight extent only. Glucose can also be fermented to a certain extent by yeast extract in the presence of arsenite.

Bacteria in flowers, D. FREIRE (*Compt. Rend. Acad. Sci. Paris, 128 (1899), No. 17, pp. 146–149*).—The author reports a number of experiments in which cultures were made in both liquid and solid media from the carpels, stamens, stigmas, and anthers of a number of cultivated flowers.

From the anthers of *Hibiscus rosa sinensis* a new species was cultivated to which the name of *Micrococcus cruciformus* was given. From the corolla of the Rothschild rose, *Leptothrix ochracea* was secured, and from a 100-leaved rose. 2 organisms, *Streptococcus pyogenes* and a new organism, *Bacillus gallicus*, were isolated. From a cardinal flower (*Ipomœa quamoclit*) 2 species were isolated, the first having the characters of *Micrococcus salivarius pyogenes* and the second was recognized as *Spirillum plicatile*. Cultures made from the flowers of the peach showed the presence of *Bacillus pyocyaneus*

The author states that in these cultures the pigments very frequently were of the same color as the flower or part of the flower from which they were taken, and he is disposed to believe that there is some relationship between the two. It was further stated that these different micro-organisms in their cultures gave off odors analogous to those of the flowers from which they were taken. For such organisms he proposes the name Osmogenic.

Bacteria in agriculture, A. J. McClatchie (*Pacific Rural Press, 59 (1900), No. 3, pp. 36, 37*).—A popular paper.

Bacteriology, A. G. Humphrey (*Trans. Illinois State Hort. Soc., 1898, pp. 235–239*).—The author discusses the significance of bacteriology in questions of human and animal sanitation and in relationship to soil problems and fermentation processes.

Bacteria; especially as they are related to the economy of nature, to industrial processes, and to the public health, G. Newman (*London: John Murray, 1899, pp. XVI + 351; rev. in Nature, 60 (1899), No. 1558, p. 434*).

Germs and their work in fermentations, J. Nelson (*New Jersey Stas. Rpt. 1898, pp. 248–287, pls. 5*).—A popular discussion is given of the subject of bacteria and fermentations brought about by their action. This article in an abridged form was published as Bulletin 134 of the station (E. S. R., 11, p. 125).

Bacteria in sanitation; their uses in agriculture, the arts, and industries, L. H. Pammel (*Iowa State Agr. Soc. Rpt. 1898, pp. 52–56*).—A popular article on the subject of germ diseases and of the activity of bacteria in other fields in relation to agriculture.

On the making and application of pure cultures, L. F. Rosengren (*Meddel. K. Landtbr. Styr., 1899, No. 56, pp. 38–44*).

On some new methods and apparatus for the bacteriological laboratory, J. Nelson (*New Jersey Stas. Rpt. 1898, pp. 243–248, pls. 3*).—Brief notes are given on fixing films to cover glasses, dilution methods for milk, counting colonies grown in tube cultures, filling culture tubes with media, a sterile water tank, a sterile milk container and pasteurizing can, dust-proof filtering bulbs and their application, universal pasteurizing and sterilizing apparatus, and on rubber caps for culture tubes.

Three newly found lactic-acid bacteria in ensiled beet chips, E. Weiss (*Jour. Landw., 47 (1899), No 2, pp. 141–161*).—Three different forms of bacteria were found, all of which produced lactic acid. These the author calls *Bacterium pabuli-acidi* I, II, III.

A sugar bacterium, H. Marshall Ward and J. R. Green (*Proc. Roy. Soc. [London], 64 (1899), No. 414, pp. 65–84*).—Studies are reported of a species of Bacterium which is associated with a yeast, the two forming a sort of excrescence on sugar cane. These clumps are said to be quite like those of the ginger-beer plant, and are used in making a fermented effervescent drink. The organism will ferment only cane and allied sugars and will not grow in acid media. Its behavior on a number of media is given, and the relation of the two organisms is discussed. There was at first thought to be a symbiosis between the yeast and the bacteria, but subsequent investigations seem to indicate that the bacterium is a saprophyte living at the expense of the nitrogenous excreta of the yeast. It is not at all parasitic, the yeast never being injured by its presence.

A soil bacillus of the type of De Bary's B. megatherium, W. C. STURGIS (*Proc. Roy. Soc. [London], 64 (1899), No. 409, pp. 340–342*).—The author describes a bacillus which was isolated from clayey and gravelly soil at a depth of about 1 inch. It is said to be straight or slightly curved, 3.4 to 7.7 μ by 1.2 to 1.5 μ in size, and occurs as isolated rods or in long chains.

The characteristics of the organism in different media and reaction toward heat, oxygen, etc., are given, and it appears to have affinities with a number of species. It seems quite near the *B. megatherium* described by De Bary and further studies may show them identical, in which case added interest will be given the subject as showing remarkable variation in the species.

Changes produced in the molecular concentration and electric conductivity of culture media produced by the growth of bacteria, G. N. SMITH (*Jour. Expt. Med., 4 (1899), No. 2, pp. 235–243*).

Decomposition of cement by bacteria, A. STUTZER and R. HARTLEB (*Ztschr. Angew. Chem., 1899, pp. 402–403; abs. in Jour. Chem. Soc. [London], 76 (1899), No. 441, II, p. 505*).

Quick vinegar bacteria, F. ROTHENBACH (*Wchnschr. Brau., 16 (1899), No. 8, pp. 100–102; abs. in Jour. Soc. Chem. Ind., 18 (1899), No. 4, p. 387*).

The nutrition of yeasts, I, A. L. STERN (*Jour. Chem. Soc. [London], 75 (1899), No. 436, pp. 201–211*).

The fermentation of raffinose by Saccharomyces pombe, H. GILLOT (*Bul. Soc. Belge Micros., 25 (1898–99), pp. 29–44*).

Ferments, E. ESTAUNIÉ (*Les ferments. Paris: Perrin & Co., 1899, pp. 353*).

The soluble ferments and fermentation, J. R. GREEN (*London and New York: The Macmillan Co., 1899, pp. XIV, 480*).

Diastase or soluble ferments, H. COUPIN (*Les diastases ou ferments solubles. Paris: Lechevalier, pp. 20, figs. 17*).

Fermentation without yeast (*Sci. Amer., 8 (1899), No. 25, p. 407*).

Recent researches on the proteolytic diastase of yeast extract, L. GERET and M. HAHN (*Ber. Deut. Chem. Gesell., 31 (1898), p. 2335; abs. in Bul. Soc. Chim. Paris, 22 (1899), No. 9, pp. 431, 432*).

The saccharification of starch by means of malt diastase, H. POTTEVIN (*La saccharification de l'amidon par la diastase du malt. Thesis, Sceaux, 1899, pp. 67*).

Concerning the glucocids and enzym found in certain species of Spiræa, M. W. BEIJERINCK (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 12, pp. 425–429*).

On the presence in the animal organism of a soluble ferment which reduced nitrates, E. ABELOUS and E. GÉRARD (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 1, pp. 56–58; 3, pp. 164–166*).

On the presence of oxidizing ferments in some phænogams, N. PASSERINI (*Nuovo Gior. Bot. Ital., 6 (1899), pp. 296–322*).

Ferments in wine diseases, J. LABORDE (*Séances Soc. Sci. Phys. et. Nat. Bordeaux, 1898, pp. 149–155*).—The bitterness of wine, or "casse," is said to be caused by ærobic organisms either completely or facultatively, and turned wines are due to either ærobic or anærobic organisms.

Studies of the Borscht or Barszcz fermentation of red beets, S. EPSTEIN (*Arch. Hyg., 36 (1899), No. 2, pp. 145–157*).

The action of formaldehyde on enzyms and on certain proteids, C. L. BLISS and F. G. NOVY (*Jour. Expt. Med., 4 (1899), No. 1, pp. 47–80*).

METEOROLOGY.

Meteorological observations, J. E. OSTRANDER and A. C. MONAHAN (*Massachusetts Hatch Met. Buls. 130, 131, 132, pp. 4 each*).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during October, November, and December, 1899. The general character of the weather of each month is briefly discussed and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

Pressure[1] (inches).—Maximum, 30.92, January 2; minimum, 29.10, December 24; mean, 30.011. *Air temperature*[2] (degrees F.).—Maximum, 93, June 5; minimum, —21.5, January 2; mean, 46.8; mean sensible (wet bulb), 43.7; annual range, 114.5; maximum daily range, 47, April 29; minimum daily range, 4.5, March 15, November 15, December 5; mean daily range, 21.2. *Humidity.*—Mean dew point, 40.1; mean force of vapor, 0.420; mean relative humidity, 75.6. *Precipitation.*—Total rainfall and melted snow, 41.49 in.; number of days on which 0.01 in. or more rain or melted snow fell, 110; total snow fall, 52 in. *Weather.*—Mean cloudiness observed, 54 per cent; total cloudiness recorded by sun thermometer, 2,210 hours, or 50 per cent; number of clear days, 81; number of fair days, 139; number of cloudy days, 135. *Bright sunshine.*—Number of hours recorded, 2,245, or 50 per cent. *Wind.*—Prevailing direction, W., SW.; total movement, 47,110 miles; maximum daily movement, 449 miles, February 13; minimum daily movement, 4 miles, December 18; mean daily movement, 129 miles; mean hourly velocity, 5.2 miles; maximum pressure per square foot, 22 lbs., or 66 miles per hour, March 7, N. E. *Dates of frosts.*—Last, May 4; first, September 14. *Dates of snow.*—Last, April 16; first, November 12.

Meteorological observations, 1890–1898, E. SIXT (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 7, pp. 546, 547*).—This is a summary by months (with averages for each year) of observations on atmospheric pressure, temperature, humidity, precipitation, cloudiness, and direction of wind.

On the mechanics of cyclones, BJERKNES (*Chem. Ztg., 23 (1899), No. 79, p. 833*).—A brief reference to a paper presented before the German Society of Naturalists and Physicians at its meeting September 17–23, 1899.

WATER—SOILS.

Investigations on the influence of salts on soil moisture, E. WOLLNY (*Vrtljschr. Bayer. Landw. Rathes, 4 (1899), No. 4, Sup. 1, pp. 137–479, fig. 1*).—This is a contribution from the agricultural experiment farm of the technical high school in Munich. Previous work along this line is briefly reviewed and experiments by the author during a number of years are reported in detail and discussed in their practical bearing. The apparatus used, a kind of lysimeter, is described and illustrated. This consists of a zinc box 30 cm. deep and 20 cm. square, closed at the bottom with a funnel for collecting the drainage water. The lysimeter is inclosed in a double-walled wooden jacket which is filled with humus soil. In the experiments reported sodium chlorid, potassium chlorid, ammonium chlorid, calcium chlorid, magnesium chlorid, sodium nitrate, potassium sulphate, sodium sulphate, ammonium sulphate, magnesium sulphate, potassium carbonate, monopotassium phosphate, and monocalcium phosphate were used at rates of 445 to 891 lbs. per acre.

The general conclusion was reached that the application of soluble salts increases the water supply of the soil and lessens the amount of water transpired by plants, but that these effects of the salts are of no benefit to the plant, because the increased growth due to the application of the salts uses more water than the soil gains as a result of the application of the salts. Moreover, in dry weather, when the moisture of the soil is of most importance, the soil solutions are likely to become so concentrated by evaporation as to partially or completely prevent the taking up of water by the roots of plants. It appears, therefore, that the benefit as regards soil moisture which on theoretical grounds would be expected from the application of soluble salts to the soil is not, as a rule, realized in practice.

---

[1] Reduced to freezing and sea level.

[2] In ground shelter, 51 ft. below level of other instruments.

Some physical and chemical peculiarities of arid soils, E. W. HILGARD (*Proc. Soc. Prom. Agr. Sci. 1898, pp. 70–76*).—This article summarizes the results of investigations at the California Station given in U. S. Weather Bureau Bul. 3 (E. S. R., 3, p. 276), as well as those of more recent studies along the same lines, which have been reported in publications of the station (E. S. R., 10, pp. 220, 225). The practical bearing of these results is briefly discussed.

The main points brought out by the investigations are as follows: The soils of the arid region are as a rule sandy, silty, or pulverulent, and rarely contain clay. Kaolinization and the subsequent formation of clay goes on in them to a very limited extent, being partially replaced by the formation of zeolitic compounds. There is practically no difference between soil and subsoil. The "sand" of such soils includes some quartz particles, but is made up largely of particles of other rock minerals. The soils are as a rule richer in plant food than soils of humid regions, this being especially true of lime (12–14 to 1), magnesia, and potash (3–4 to 1). The humus content is smaller, but the amount of nitrogen is about the same, since the humus of arid soils is from 3 to 5 times as rich in nitrogen as that of humid regions. Nitrification is also more active and the nitrates are not leached out.

"The occurrence of 'alkali' salts in the soils of the arid regions is independent of either present or former marine conditions. The salts are the educts of the soil from the weathering process, and in consequence of deficient rainfall have failed of being leached into the subdrainage. They very commonly contain notable amounts of water-soluble potash salts, also nitrates, and frequently alkali phosphates. Aside from these water-soluble ingredients, alkali soils always contain large amounts of acid-soluble plant food.

"The presence of alkali carbonates (usually the sodic salt) acts most injuriously, not only in being directly corrosive of the bark of roots and stems, but also in so deflocculating the soil as to render tillage and drainage impossible. This can be remedied by the transformation of the sodic carbonate into sulphate, by means of land plaster in the presence of water; soils so treated become profusely productive, unless overcharged with sodic salts.

"Outside of the axes of valleys, the alkali salts are usually contained within the first 4 ft. from the surface down. Within this limit they migrate up and down according to the moisture conditions, but are apt to accumulate particularly at the average depth to which the annual rainfall penetrates. We can therefore ascertain, by the examination of a 4-ft. column of soil, the total amount of salts which, under favorable conditions, may either accumulate within 6 in. of the surface or be more or less evenly distributed through the soil column. We can thus determine beforehand the practicability of reclaiming such lands for cultivation under existing economic conditions, taking into consideration the ascertained toleration of the salts by the several crops."

The physical conditions of arid soils are especially favorable to extensive root growth and to the capillary rise of water, thus enabling plants to grow with a limited amount of water in the soil. The alkali salts present also assist in collecting and conserving moisture. The abundant supply of readily available plant food present, even in the coarse-grained soils, contributes to the vigorous growth of plants.

A study of the native vegetation has shown "what plants indicate, in California, [alkali] land which under present economic conditions is irreclaimable; while it has been as definitely shown that the presence of certain other plants, known to be tolerant of alkali, indicates that certain crops can be grown successfully."

An investigation of cranberry soils (*New Jersey Stas. Rpt. 1898, pp. 122-124*).—Mechanical and chemical analyses of soils from bogs producing healthy and unhealthy (rotting) berries and chemical analyses of healthy berries and healthy and unhealthy vines are reported. These show that soils on which the berries did not rot contained more silt and clay and iron and aluminum and less nitrogen than those producing diseased berries. The vines which produced rotten fruit contained much less potash and phosphoric acid than those which bore sound fruit.

"The same is true in a less degree in the case of soda, lime, and sulphates. The differences in nitrogen which were in the soils did not appear in the vines. The analysis of good berries themselves indicates that the same mineral constituents, and especially the potash and phosphoric acid, and to a smaller degree the lime, are essential to the healthy growth of this fruit.

"In view of these results, together with the good effects from the addition of clay to many bogs, which contributes to both their mechanical and chemical improvement, the Station suggests that in the case of rotten bogs, a liberal application of phosphoric acid and potash might, in part at least, correct the deficiencies which are shown to exist in the soils and vines from bogs producing rotten fruit, the phosphoric acid to be drawn preferably from natural guanos, or from basic slag phosphate, and the potash to be in the form of a sulphate."

On the sterilization of water by means of ozone, T. WEYL (*Chem. Ztg., 23 (1899), No. 78, p. 816*).

The influence of forests on moisture, BUHLER, EBERMAYER, HOPPE, and MÜTTRICH (*Ztschr. Forst u. Jagdw., 31 (1899), No. 9, pp. 547-551*).—An outline report is given of suggested investigations on the influence of forests on precipitation, water conservation, etc.

Influence of forests on subterranean waters (*Agr. Gaz. New South Wales, 10 (1899), No. 12, pp. 1264-1267*).—A brief review mainly of articles by Brouillard, Henry, and Ototzky (E. S. R., 9, p. 1041) on this subject.

Analysis of cocao soils from Venezuela and Trinidad, P. CARMODY (*Abs. in British Food Jour., 1 (1899), No. 7, pp. 210-211*).—Gives results of analyses by the Government analyst of Trinidad.

FERTILIZERS.

Fertilizers, S. W. JOHNSON, E. H. JENKINS, ET AL. (*Connecticut State Sta. Rpt. 1898, pp. 1-101*).—This includes statistics of fertilizer sales in Connecticut in 1898, an abstract of State laws relating to fertilizers, a list of manufacturers complying with the laws, notes on the sampling and collecting of fertilizers, explanations concerning the analysis and valuation of fertilizers, a review of the fertilizer market for the year ended October 31, 1898, suggestions regarding the purchase of fertilizers, and tabulated analyses and valuations of 569 samples of fertilizing materials classified as follows: (1) Raw materials containing nitrogen as the chief valuable ingredient—nitrate of soda, sulphate of ammonia, dried blood, cotton-seed meal, castor pomace, and rape-seed meal; (2) raw materials containing phosphoric acid as the chief valuable ingredient—rock phosphate, dissolved boneblack, and acid phosphate; (3) raw materials containing potash as the chief valuable ingredient—high-grade sulphate of potash, double sulphate of potash and magnesia, muriate of potash, kainit, carbonate of potash, silicate of potash, phosphate of potash, and tobacco stems; (4) raw materials containing nitrogen and phosphoric acid—bone manures, tankage, and fish; (5) mixed fertilizers—bone and potash, nitrogenous superphosphates and guanos, special manures, and home mixtures; (6) miscellaneous fertilizers and manures—cotton-hull ashes, corncob ashes, wood ashes, limekiln ashes, lime, marl, plaster, bat guano, street sweepings, ground weed seed, jadoo fiber, and rotted peat.

The samples of nitrate of soda examined were of good quality, the price per pound of the nitrogen which they furnished varying from 12.7 to 14.7, averaging 13.5 cts.—1 ct. less than last year. In 2 samples of sulphate of ammonia analyzed the price per pound of nitrogen was 14.3 and 15.5 cts.; in 2 samples of dried blood, 11.4 and 13.1 cts. In 34 samples of cotton-seed meal the percentage of nitrogen ranged from 7.04 to 7.97, averaging 7.44, the price per pound of nitrogen from 10.2 to 12.4, averaging 11.5 cts., "the cheapest form of quickly available organic nitrogen in our market." Five samples of castor pomace were examined, the percentage of nitrogen ranging from 4.60 to 5.70; the price per pound of nitrogen from 14.7 to 18.3 cts.

The cost of available phosphoric acid in dissolved boneblack ranged from 6 to 6.9 cts. per pound, the average in 7 samples being 6.5 cts. In 6 samples of dissolved rock phosphate, the cost of available phosphoric acid varied from 3.1 to 7.4 cts. with an average of 3.9 cts.

The cost of potash in 5 samples of high grade sulphate varied from 4.6 to 5.1 cts. per pound, averaging 4.8. In 8 samples of low grade double sulphate of potash and magnesia, the cost ranged from 4.9 to 6.8 cts., with an average of 5.8 cts. per pound. In 11 samples of muriate of potash, the cost per pound of potash ranged from 3.8 to 4.5 cts., averaging 4.2 cts., "the cheapest source of water-soluble potash in the market." The cost of potash in kainit varied from 5.1 to 6.3 cts. per pound.

"Of the 119 analyses of nitrogenous superphosphates examined, 23 were below the manufacturer's minimum guarantee, in respect of 1 ingredient, and 3 in respect of 2 ingredients. The number which failed to come up to the guarantee was relatively about the same as in the previous year. . . . The average cost of the nitrogenous superphosphates was $29.22; the average valuation was $19.30. . . .

"Of the 111 samples [of special manures] analyzed, 33 did not fulfill the manufacturer's minimum guarantee in respect of 1 ingredient, and 6 were each deficient in respect of 2 ingredients. . . . Thirteen were deficient in nitrogen, 22 in potash, and 10 in phosphoric acid. In 8 of the 10 cases, however, the available phosphoric acid was as guaranteed, the deficiency being only in the insoluble part of the phosphoric acid. The average cost per ton of the [special manures] examined was $33.11; the valuation, $21.72."

In 47 samples of cotton hull ashes the highest percentage of potash found was 31.09, the lowest 15.08, the average 23.3. "Allowing 4½, 4, and 2 cts. per pound respectively for water-soluble, citrate-soluble, and insoluble phosphoric acid, the water-soluble potash has cost from 4.8 to 10.7 cts. per pound, or 7.1 cts. per pound on the average."

Fertilizers (*New Jersey Stas. Rpt. 1898, pp. 15–87*).—This is a reprint of Bulletin 132 of the station (E. S. R., 10, p. 1031), with the addition of statistics of the fertilizer trade in New Jersey, the market prices of fertilizers, the text of the fertilizer law, and lists of inspectors and of manufacturers whose goods were inspected during 1898.

From the data furnished by 75 out of the 90 firms selling fertilizers in the State it is estimated that the total consumption of fertilizers in New Jersey in 1897 was 56,172 tons (about 200 tons less than in 1896), valued at $1,551,073. "The complete manures represented 73 per cent of the total number of tons sold in 1897, and 78 per cent of the total value of all sales."

"There was a decrease in the sales of complete fertilizers, due partly to the fact that the season was a poor one, and partly to the constantly increasing tendency among the farmers toward the purchase of raw materials. The sale of these 'incomplete' fertilizers has increased in a striking manner during 1897; all of the raw materials, with the exception of the superphosphates, show large gains over 1896, varying from 8 per cent in the case of kainit to 230 per cent in the case of sulphate of potash."

Methods to determine the availability of organic nitrogen in fertilizers, J. P. STREET (*New Jersey Stas. Rpt. 1898, pp. 88–100*).—This article reports the individual results of tests of the pepsin method on complete fertilizers, a summary of which was given in the Annual Report of the station for 1896 (E. S. R., 9, p. 637), as well as further investigations by means of vegetation experiments and the permanganate and pepsin methods.

For the vegetation experiments boxes 18 in. square and 12 in. deep were used. The artificial soil used (about 75 lbs. in each box) was sifted coal ashes with 3 per cent of muck containing 0.86 per cent of nitrogen. To each box was added 30 gm. potassium phosphate, 1.5 gm. sodium chlorid, 2 gm. magnesium sulphate, and 96 gm. calcium carbonate. Amounts of nitrate of soda, dried blood, tankage, cotton-seed meal, hoof meal, raw bone, and raw leather furnishing 5 gm. of nitrogen were used. The crop grown was oats, 50 plants in each box.

The amount of nitrogen in the above-ground crop indicated a wide variation in the availability of the nitrogen of the different materials, "ranging from 4.9 per cent in the case of leather to 33.1 per cent where nitrate of soda was used."

"The fact that only 33.1 per cent of the nitrogen applied as nitrate of soda was utilized by the plants shows that a large amount still remained in the soil. The small amount which the roots would contain would not affect these figures materially. It would seem, therefore, that in planning the experiment an excessive amount of nitrogen was used, and the percentage availabilities found for that reason can not be regarded as conclusive. They do show, however, wide differences in the availability of the different forms of organic nitrogen. Hoof meal and dried blood stand highest, with 27.5 and 27.4 per cent available, while tankage and cotton-seed meal are considerably less, with 23.1 and 20.6 per cent, respectively. Raw leather, 4.9 per cent, is the lowest, showing this form to be comparatively inert, while raw bone gives an availability of but 10.3 per cent. This figure, however, does not show that the nitrogen of ground bone is necessarily inferior to that of other organic nitrogenous materials, as ground bone is most successfully used on grass, clover, and fruits, which are not annual crops, and which extract plant food from the soil more or less actively during prolonged periods."

The materials used in the above experiments, as well as dry ground fish, wool waste, bone sawings, and steamed bone, were tested by the permanganate and pepsin-hydrochloric acid methods.

The permanganate methods used were as follows:

"*Method in acid solution.*—Weigh 1 gm. of material into a 500 cc. flask, add a little paraffin and 100 cc. of permanganate solution (consisting of 16 gm. of potassium permanganate and 100 cc. of concentrated c. p. sulphuric acid to the liter). Connect with distilling apparatus and heat at a low temperature just below boiling for 1 hour. Then add 50 cc. of saturated sodium hydrate solution, distill for 30 minutes, and tritrate as usual.

"*Method in alkaline solution.*—Weigh 1 gm. of material into a 500 cc. flask, add a little paraffin and 100 cc. of permanganate solution (consisting of 16 gm. of potassium permanganate and 300 cc. of saturated sodium hydrate solution to the liter). Connect as before and heat below boiling point for 1 hour. Then increase the temperature and distill for 30 minutes as above. . . .

"After making a number of tests it became evident that the method, as suggested, was a difficult one to control. The directions provided that during the digestion the solutions should be heated just below boiling. This was found to be almost an impossibility, and it was very difficult to maintain uniform conditions in 2 different sets of tests. The results showed the 3 forms of bone to be the most available, while the others follow in this order: tankage, wool waste, fish, hoof meal, blood, cotton-seed meal, and leather. These results were far from satisfactory, as it was known that, with the exception of the leather, the order of their availability should be almost reversed."

The following method was tested with more satisfactory results on a great variety of nitrogenous materials:

"Weigh an amount of the material equivalent to 0.075 gm. of nitrogen into a 500 cc. Erlenmeyer flask, add 100 cc. of neutral 1.6 per cent permanganate of potash solution, and digest on a steam bath for 30 minutes, shaking occasionally to moisten any particles of the material adhering to the sides of the flask. Filter and wash 3 or 4 times, using from 125 to 150 cc. of water. Determine the total nitrogen in the undigested residue by the ordinary Kjeldahl method. . . .

"The results secured by this treatment are remarkably striking, the difference in the effect of the permanganate solution of the various ammoniates being very noticeable. The percentage availability varies from 95.9 per cent in horn to 25.5 per cent in raw leather. The other materials range in availability between these limits in the approximate order one would expect vegetation cultures to show. The ground horn sample is possibly somewhat above the average of that material, it having been carefully prepared in this laboratory and being nearly 5 years old. . . .

"Of the 3 classes of bone examined, the steamed bone shows the highest degree of availability. This is doubtless due to the fact that the process of steaming had in a large measure removed the fatty matter. The hard button bone ranks next in availability, while the raw bone meal, in which much fat was present, ranks lowest of the 3 forms of bone examined. The availability of the dissolved bone is slightly below that of raw bone, seeming to indicate that the treatment with sulphuric acid had little effect on the nitrogenous matter in the bone. The 2 samples of garbage are low in availability, as would be expected, as are also the various samples of leather.

"These results show that striking and reasonable differences in availability may be secured by this method, and while definite conclusions can not be drawn from them in the absence of actual tests with the plant itself, they do give indications of much promise in the effort to secure a rapid and accurate method for laboratory practice."

On the availability to grass of nitrogen in form of nitrate of soda, cotton-seed meal, and fine hard bone, E. H. JENKINS and W. E. BRITTON (*Connecticut State Sta. Rpt. 1898, pp. 289–296*).—This is a continuation of previous investigations (E. S. R., 10, p. 232). The pots used were like those employed in earlier experiments, and the methods pursued were in general the same. The soil experimented with contained about (slightly less than) 0.1 per cent of nitrogen. Precipitated calcium carbonate was added at the rate of 9.5 gm. per pot (containing 29 lbs. of soil), or the equivalent of 1 ton of slaked lime per acre; muriate of potash 1.8 gm. per pot or 500 lbs. per acre; and precipitated phosphate 1.2 gm per acre, or the equivalent of about 1,000 lbs. of acid phosphate per acre. The 3 nitrogenous substances were added at rates furnishing equal amounts of nitrogen as follows: Nitrate of soda (15.89 per cent of nitrogen) 461 and 331 lbs. per acre, cotton-seed meal (7.4 per cent of nitrogen) 991 and 496 lbs., and pure raw knuckle bone (3.67 per cent of nitrogen) 1,990 and 995 lbs. The amount of moisture in the soil was maintained at from 11.6 to 15.5 per cent, or 50 to 70 per cent of that which it could hold if saturated.

Three small sets cut from a tuft of redtop were planted in each pot.

"The pots were filled and planted February 14 to February 17, and stood till June 10 in the greenhouse, having a temperature by day of about 60° F. and by night about 50° F. During the summer the pots were placed in the summer vegetation house, and brought into the greenhouse again in October.

"The grass was cut whenever it reached a length of 3 or 4 in., thus imitating the practice of grazing or lawn-mowing, and all the clippings were carefully saved.

"In early summer nitrogen was determined in the 3 clippings which had been already made, and again in the fall it was determined in the next 3 clippings. The first 3 clippings were made on March 31, April 27, and June 7. The 3 later cuttings were made July 11, August 29, and October 1. After the last cutting the growth was very slow, and the grass in every pot looked yellow, as if starving. A seventh cutting was, however, made on January 7, 1899."

The data, which are tabulated, show that when nitrate of soda was applied at the rate of 461 lbs. per acre (73 lbs. of nitrogen) 90 per cent of the nitrogen was recovered in the crop, which was increased 31.7 per cent; when an equal amount of nitrogen in form of cotton-seed meal was used 50 per cent of the nitrogen was recovered, the crop being increased 6.3 per cent; while with the same amount of nitrogen in fine hard raw bone only 5 per cent was recovered and the crop was not increased.

"When half the quantities of nitrogen named above were used, the following percentages of the fertilizer nitrogen were recovered in the crops: From nitrate of soda, 77 per cent; from cotton-seed meal, 66 per cent; from bone, none."

With the smaller quantities of nitrogen the yield was increased in case of nitrate of soda 5.6 per cent, of cotton-seed meal 2.1 per cent. In case of the bone there was a decline in yield.

"It appears that the effect of the nitrogenous fertilizers on the amount of crop nitrogen was shown chiefly in the first 3 clippings [these being much richer in nitrogen than the later clippings]. In the second half of the year the yield of nitrogen was not very much larger on those pots which had received fertilizer nitrogen than on those which had received none.

"But, on the other hand, the gross yield of air-dry crop was considerably greater in the latter part of the year than in the early part immediately following the application of the nitrogenous matters."

Phosphates, 1899, E. WILLIS (*Tradesman, 42 (1899), No. 9 (21 annual), pp. 137, 138*).—A summary of the trade in phosphates, especially in the United States. The total production in the United States in 1899 is stated to be: Florida phosphate 858,975 tons, South Corolina phosphate 419,763 tons, Tennessee phosphate 500,000 tons, North Carolina phosphate 13,000 tons; total, 1,791,738 tons.

Complete analysis of phosphate from the island of Fernando Noronha, Brazil, H. LASNE (*L'Engrais, 14 (1899), No. 50, p. 1189*).—The sample analyzed contained 86.5 per cent of calcium phosphate, 5.6 per cent of calcium carbonate, and 2 per cent of iron oxid and alumina.

The black phosphates of the Pyrenees (*L'Engrais, 14 (1899), No. 51, pp. 1212, 1213*).—See E. S. R., 10, p. 833.

Phosphate deposits in Japan, K. TSUNETO (*Chem. Ztg., 23 (1899), Nos. 77, p. 800; 79, pp. 825–827*).

Effect of nitrogenous fertilizers on the percentage of protein in grasses and legumes, C. S. PHELPS (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 130–136*).—This is a brief summary of experiments which have been carried on at the Connecticut Storrs Station for several years and have been reported upon from time to time in the publications of that station (E. S. R., 9, p. 746). In these experiments the use of nitrogenous fertilizers resulted in an increase of both yield and nitrogen content of grass, corn, rye, oats, and wheat.

On the sulphur in plants, S. BOGDANOV (*Zhur. Russ. Fiz. Khim. Obshch., 31 (1899), No. 4, p. 471; abs. in Bul. Soc. Chim. Paris, 3. ser., 22 (1899), No. 23, p. 965*).—From the beneficial effects of fertilizers containing sulphates the author concludes that sulphur is of more importance in plant growth than is usually assumed. The methods of Liebig, Carius, Stoeckhardt, and Schraeder for determining sulphur were compared on cereals, leguminous plants, and beets. Liebig's method is preferred for accuracy and simplicity. Nearly 12 times as much sulphur was found in the products examined as appears in their ash. In view of this fact the author thinks that the question of exhaustion of sulphuric acid in the soil is of practical importance.

FIELD CROPS.

The culture of buckwheat, S. BOGDANOV (*Selsk. Khoz. i Lyesov., 193* (*1899*), *Aug., pp. 227-271*).—A study is being made of the buckwheat plant in Russia for the purpose of determining a more rational system of its culture. The results of the first season's work are recorded and a review given of the literature of the subject.

The buckwheat selected for study was *Fagopyrum esculentum aptera.* It was grown in the Botanical Gardens of Kiev University on a clayey soil. Plants were taken for analysis every 2 weeks. The following table shows the average weight of the plants at different stages of growth and some of the more important mineral constituents:

Weight per plant and analysis of buckwheat (*roots and vines*) *at different stages of growth.*

Date sample was taken.	Average weight of plant.		Analysis of air-dried plant.					
	Fresh.	Air dry.	Moisture.	Nitrogen.	Phosphoric acid.	Potassium oxid.	Calcium oxid.	Sulphur.
	Grams.	*Grams.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
May 31	0.212	0.020	7.163	2.484	2.589	5.314	1.298	0.441
June 16	.781	.076	9.702	2.389	2.099	5.905	1.514	.307
July 2	2.771	.353	8.517	1.800	1.703	4 815	.979	....
July 16	3.108	.622	8.191	1.376	1.318	2 872	.779	.238
July 29	2.158	.658	8 087	1.098	.946	2.734	1.763	.273
August 6	2.491	1.035	8.105	1.006	1.204	2.627	2.192	.388

It will be seen from the table that the greatest increase in dry matter takes place during the later growth of the plant, and that there is quite a regular decrease in the percentages of nitrogen, phosphoric acid, and potash as the plant develops. This decrease is not observable in the case of lime and sulphur.

Comparing the demand on the soil made by buckwheat with that of oats, the author finds that in order to obtain even a low yield of oats the soil must contain much more nitrogen and somewhat larger quantities of other nutrient materials than are required for a crop of buckwheat.

The 2 latest cuttings of buckwheat were examined for chlorin. The sample analyzed July 29 contained 0.04 per cent and the sample analyzed August 6, 0.07 per cent. The author thinks it doubtful whether chlorin plays the important part in the growth of buckwheat ascribed to it by both scientists and practical growers.

If the sulphur contained in the buckwheat August 6 is taken as 1, the nitrogen will be represented by 2.6, phosphoric acid by 3.1, potash by 6.8, and lime by 5.6. These figures are taken as furnishing valuable hints as to the fertilizers required by buckwheat, i. e., the relative unimportance of nitrogen and the very great need of potash and lime. The proportionately large percentages of nitrogen, phosphoric acid, and potash found in the early vegetation periods of buckwheat plants, would seem to show the desirablity of applying fertilizers in the early stages of growth and in such a position that the young rootlets may readily find them.

The method of root development of buckwheat was especially studied. The root of the buckwheat plant first penetrates into the soil vertically, forming no laterals. Later on laterals are formed, beginning at the upper portion of the main root. At a certain period of development the main root ceases development but the laterals, especially the upper ones, still continue to multiply and increase in length until the plant matures.—P. FIREMAN.

The manuring of cotton, G. P. FOADEN (*Jour. Khedivial Agr. Soc. and School Agr., 1 (1899), No. 6, pp. 207–214*).—This is a brief discussion of the manuring of cotton in Egypt, in which is incorporated the results of some experiments made by the Khedivial Agricultural Society, with barnyard manure, poudrette, and guano. The principal conclusions drawn are that the cotton crop in Egypt is benefited by the judicious use of fertilizers. Fresh barnyard manure is not a desirable fertilizer for this crop, but poudrette of the best quality applied at the rate of 1⅕ tons per acre gave excellent returns. Poudrette and other manures applied in excessive quantities did not give profitable returns. Guano proved to be a valuable fertilizer. Judicious manuring hastened the ripening of the crop, consequently a greater proportion of the total yield was obtained at the first picking and the crop was therefore more valuable.

Hop cultivation in Bohemia, D. G. FAIRCHILD (*U. S. Dept. Agr., Division of Botany Circ. 19, pp. 6*).—A popular account of hop culture and management in Saaz and Auscha, "the two most noted hop growing districts of Bohemia." Male plants are not permitted to grow in the hop yards in these districts, and hops containing over 0.2 per cent of seed are rated as second class. In Saaz a house has been erected for the benefit of buyers by the Hop Growers' Association of the city, which certifies to the quality of the hops grown in the different parts of the district. The Auscha red hop is the principal variety grown in both districts. This hop brought 58 cts. per pound in American markets when native hops were selling for 19.5 cts. per pound. Cuttings of this hop have been ordered by the Department for importation in 1900.

Fertilizer experiments with barnyard manure on sugar beets (*Deut. Landw. Presse, 26 (1899), No. 93, pp. 1047, 1048*).—The barnyard manure employed was obtained (1) from deep stalls in which 20 steers had been fed and (2) from ordinary stalls, the steers receiving in both cases the same rations, and the manure being in part preserved under cover and in part exposed to the elements. The fertilizers were applied at the rate of 800 kg. of barnyard manure and 800 kg. of nitrate of soda per hectare. To avoid the loss of ammonia, a weak solution of sulphuric acid was sprayed over a part of the stable manure at the time of its removal to the field. Analyses of the fertilizers preserved under different conditions are given, and the total yields and percentages of sugar in beets grown on plats differently fertilized tabulated.

Considering the results with the manures unsprayed with sulphuric acid, the largest total yield of both roots and leaves was obtained from the field fertilized with manure from the deep stalls. The sugar in the beets was 0.5 per cent less than in the beets grown on the plats fertilized with the manure from the ordinary stalls, but the total yield per hectare, 7,674 kg., was 694 kg. more than was obtained on the plat fertilized with barnyard manure preserved under shelter and 998 kg. more than the yield with barnyard manure which had been exposed to the elements. When the manures were sprayed with a dilute solution of sulphuric acid, the yields of both roots and tops were considerably increased, except in the case of the unsheltered manure, where they were slightly lessened. The largest total yield of sugar beets per hectare was obtained from the plat which had been fertilized with the sheltered, acid-sprayed manure from the ordinary stalls. This yield was at the rate of 49,872 kg. of roots, 20,800 kg. of tops, and 8,329 kg. of sugar per hectare, the purity of the sugar in the juice averaging 90.2 per cent.

Spraying was not found a satisfactory method of incorporating sulphuric acid with barnyard manure, and it is suggested that a better method would be to soak a mixture of sand and peat in the dilute acid and mix this with the manure as it is removed from the stalls.

Cultivation of cigar-leaf tobacco in Florida, M. L. FLOYD (*U. S. Dept. Agr., Rpt. 62, pp. 31, pls. 8, figs. 6*).—The introduction into Florida within recent years of Cuban tobacco for cigar-leaf fillers and Sumatra for wrappers has greatly stimulated the tobacco industry in this State and led to improved methods of culture and handling. The bulletin in hand summarizes the progress along these lines thus far made and gives the present status of the industry within the State. The author discusses in detail the requirements of the cigar-leaf trade; the field culture, harvesting, curing, fermenting, grading, sorting, and baling of Florida-grown Cuban tobacco; the selection and preparation of the seed bed for Sumatra tobacco; field work required in its production, and the relative value of new and old land for its growth; and gives plans and specifications for the building of tobacco barns and for the cost of opening and operating a 500-acre tobacco plantation.

Light gray sandy loam soil with a clay subsoil is recommended for Cuban tobacco and new low hummock land for Sumatra. At the present time Cuban tobacco is set 14 in. distant in the row, well fertilized, and 16 leaves at least left to each stalk after topping. Cultivation stops as soon as the tobacco is topped. In the culture of Sumatra tobacco a very rich soil and quick growth are required. Each stalk is left with 24 to 30 leaves after topping. If the soil is very rich topping is omitted entirely. The plants are set from 12 to 14 in. in the drill. New lands are especially desirable for this tobacco, though good results have been obtained on well-fertilized old soils.

One of the most important innovations in the growing of tobacco in Florida is the introduction of shade sheds, made either of slats or cheese cloth. The slat sheds are covered with 2-inch slats placed 2 in. apart. The cheese-cloth sheds consist of a framework covered with cheese cloth. In 1898 one tobacco firm in Gadsden County planted 200 acres of tobacco under shade. A yield of 800 lbs. per acre, with 50 per cent wrapper, is reported. About 600 acres were planted under shade in this county in 1899.

The cost of raising tobacco on large plantations is estimated at 18½ cts. per pound. Small farmers who raise tobacco in connection with other crops report the cost as being between 10 and 12 cts. per pound. The finished product from the small farms is generally inferior to the well-cured product of the larger plantations. Well cured and baled Florida fillers sell for as high as 45 cts. per pound, while wrappers bring from 50 cts. to $2 per pound, according to style and quality.

Curing and fermentation of cigar-leaf tobacco, O. LOEW (*U. S. Dept. Agr., Rpt. 59, pp. 34*).—The author discusses the chemical and physiological changes which occur in the different processes of curing, sweating, after fermentation or aging, and petuning of tobacco, and the bacterial fermentation theory of Suchsland; and presents the results of his own investigations on the curing and fermentation of tobacco, involving bacteriological, chemical, and chemico-physiological studies. A short bibliography of recent foreign literature bearing on the subject is appended.

While it is generally admitted that the so-called fermentation of tobacco is a process of oxidation, authorities differ regarding the causes. The views of Nessler, Schloesing, and Suchsland are discussed. The latter holds (E. S. R., 3, p. 354) that the oxidation and development of heat are due to the action of certain bacteria. The author believes this theory to be erroneous, since he finds no bacteria in the cells or on the surface of fermenting Florida tobacco leaves, although some spores may occur. While in the process known as petuning an immense number of bacteria may be deposited on the leaf, they are not essential to fermentation. There is under the most favorable condition insufficient moisture in fermenting tobacco to bring nourishment to the bacteria on the surface from the interior of the leaf. Should water exist in excess, bacterial action may set in, but to the detriment of the structure of the leaf. Finally, as the tobacco approaches the end of the fermentation process, it becomes less fit to support bacterial life, as was shown by experiment. The theories of Nessler and of Schloesing as to the cause of the oxidizing action are also opposed.

As a final agent capable of causing the energetic oxidizing action which takes place in the tobacco cells after death the author suggests that of oxidizing enzyms. The nature and occurrence of enzyms and their action toward certain reagents are discussed in considerable detail, and the views of the author and others given on the physiological functions of oxidizing enzyms.

The investigations of the author lead him to conclude that—

> "There exist, evidently, 2 kinds of oxidizing enzyms in the Florida tobacco leaf. The first kind oxidizes guaiaconic acid to guaiac blue without the aid of peroxid of hydrogen, but the second kind oxidizes it only when this substance is present. Both kinds of oxidizing enzyms, which may be distinguished as tobacco oxidase and tobacco peroxidase, occur in the fresh as well as in the recently fermented Florida tobacco leaf. The former enzym is, however, much more sensitive to heat than the latter, being killed at from 65 to 66 C. (149 to 151° F.), while the latter is killed only at from 87 to 88° C. (188.6 to 190.4° F.)."

Dark Florida tobacco 2 years old yielded no reaction for tobacco oxidase and only a moderate one for tobacco peroxidase, "while a sample of light-colored tobacco 4 years old from the same source yielded not the slightest reaction either for the oxidase or the peroxidase." Both the oxidase and the peroxidase occur in young tobacco plants, and in the fresh tobacco leaf they were found in the ribs and veins as well as the parenchyma.

> "The bundle sheath and sieve tissue give the most intense reaction on the oxidase, while the reaction on the peroxidase sets in quickly and with about uniform intensity in all the cellular tissues. The growing point and youngest leaves contain an especially large quantity of the oxidase. A section through the stalk shows oxidase only in the sieve tissue and bast parenchyma, while peroxidase also is contained in the pith. Both enzyms are found in the root, the former more in the central and the latter in the peripheral parts and also in the flower. The stigma of the pistil and the stigmatic fluid also show strong reaction upon oxidase."

Directions are given for obtaining colorless solution of tobacco peroxidase and for the complete extraction of oxidases from fermented and cured tobacco. The oxidase is thought to be the more powerful, but it more quickly succumbs to alcoholic influence or a rising temperature. The oxidase was found by experiment to bear more resemblance to laccase than to tyrosinase.

In order to prove that the oxidizing enzyms contained in tobacco leaf can decompose nicotin, 50 gm. of unfermented Connecticut tobacco, which showed a strong reaction for peroxidase but none for oxidase, was thoroughly moistened with water, and allowed to stand for 2 days in a 250 cc. solution of 50 per cent alcohol. The liquid obtained by pressing was mixed with 1½ times its volume of absolute alcohol and a brown-colored precipitate, containing a large proportion of peroxidase obtained. The precipitate was dissolved in 20 cc. of water and 0.5 gm. of nicotin tartrate added. This mixture was digested for 2 days at from 50 to 60° C. in a 500 cc. flask, to which a small U tube containing a dilute solution of chemically pure sulphuric acid was attached. An examination of the acid at the end of this period revealed the presence of small amounts of ammonia, and still larger amounts of nonvolatilized ammonia were found in the mixture itself.

The following are among the author's conclusions:

"The principal changes that take place during the curing and fermenting of tobacco are due to the action of soluble ferments or enzyms.

"Several kinds of enzyms act in the curing process, (1) an amylolytic, (2) a proteolytic, and (3) 2 oxidizing enzyms, while in the fermenting process the main changes are due to oxidizing enzyms alone, and consist in the oxidation of nicotin and other compounds.

"The presence of the amylolytic and the proteolytic enzyms is inferred from the saccharification of the starch and the decomposition of proteids, but the enzyms themselves have not yet been isolated from the tobacco leaf.

"In green tobacco 2 oxidizing enzyms may exist—an oxidase and a peroxidase. The former succumbs much more readily to noxious influences than the latter and in all probability exerts a more powerful action.

"The development of color and aroma is due principally to the action of the oxidizing enzyms."

Temperature changes in fermenting piles of cigar-leaf tobacco, M. WHITNEY and T. H. MEANS (*U. S. Dept. Agr., Rpt. 60, pp. 28, charts 7*).—Results are given of some investigations upon the temperature changes in fermenting tobacco in Florida and Connecticut, together with a résumé of Loew's investigations on the cause of tobacco fermentation (see above) and of the method of fermenting tobacco employed in Florida (E. S. R., 10, p. 748).

The data secured in Florida are given in tables and charts and discussed. The results show that in fermenting Florida leaf tobacco a moisture content of 23 or 24 per cent is most advantageous for best results. Twenty per cent is too low for the full activity of the enzyms causing fermentation, while 26 per cent is too high and furnishes conditions favorable to the development of rot or mold. The relative humidity for the fermenting room for Florida leaf tobacco should be maintained at 80 or 90 per cent, while the temperature should range from 70 to 80° F. during active fermentation, and for the so-called cold fermentation from 60 to 70° F. With these conditions maintained, the temperature in the center of the piles should rise from 8 to 10° F. per day until it reaches 130 to 135° F., when the piles should be rebuilt and the operation again started. The rebuilding of the bulk from 6 to 8 times is necessary usually before the operation of active fermentation is completed. The wrapper leaves are bulked in a drier condition and the temperature is not allowed to rise higher than 110 to 120° F.

A trial of the Florida methods of fermentation with Connecticut tobacco showed that the latter did not reach a higher temperature than 100° F. under conditions similar to those in which the Florida leaf had risen to 144° F. An examination of the Connecticut leaf showed the absence of oxidase, though peroxidase was present. The former enzym, however, was found in the growing Connecticut tobacco plant. The course of disappearance of this enzym between the time the tobacco is cut and the period of fermentation is being studied.

Experiments in curing and fermenting tobacco, E. H. JENKINS (*Connecticut State Sta. Rpt. 1898, pp. 297–301*).—These experiments are in continuation of those previously reported (E. S. R., 10, p. 242). A detailed description is given of a new curing barn in which artificial heat may be used. The crop secured in 1898 was light and of rather poor quality. It was hung in the barn and cured in the usual manner, except that in the evening and in unfavorable weather artificial heat from the furnace was employed. The object of using artificial heat was to maintain constantly the best natural conditions for curing tobacco and to protect the tobacco from chilling, from the deposit of water on it, and from alternate dampening and drying. The curing operations in the new barn were entirely successful. The tobacco put in the barn July 29 had come to color August 20. From the results of the experiment the author is confident that "the use of artificial heat in some form will make the curing of tobacco less hazardous and give a better average quality of leaf."

The loss of water in tobacco during the curing process was investigated. Six plants were weighed at harvest time and at different periods thereafter until the tobacco was cured. From the results obtained it is calculated that the 24,160 lbs. of green tobacco put in the barn July 29 had decreased in weight from loss of moisture to 5,332 lbs. on September 23.

The fermentation of tobacco in bulk, E. H. JENKINS (*Connecticut State Sta. Rpt. 1898, pp. 302–307*).—The author gives results of efforts to ferment Connecticut tobacco in bulk by the methods practiced in the South (see p. 729). The usual practice in Connecticut is to ferment in cases. The sorted leaves are tied into "hands" containing 13 to 20 or more leaves, and packed into cases of about 300 lbs. each. These cases are allowed to ferment naturally during one summer and are sold at the end of that period by sample. There is no control ot the operation and its success is in doubt until the operation is completed. Frequently the operation of fermentation is hastened by putting the cases in a room heated to 90, 100 or even 130° F. In this way the tobacco is made ready for market in 6 or 8 weeks from the time it is cased.

In order to test the bulk method of fermentation, a basement room having a steam pipe running through it was fitted up. By means of a steam cock the average temperature in the room during fermentation was maintained at about 82° F. and the relative humidity at about 80 per cent. The first bulk fermented contained 930 lbs. of tobacco—314 lbs. of top leaves and 616 lbs. of bottom leaves. The top leaves were judged to be in a good condition of fermentation, but the seconds were considered too dry. "The temperature of the top of the bulk arose to 100° F. in 9 days, or at the rate of 4° in 24 hours. The temperature of the center rose to 102° F. in the same time, or at the rate of 4½° in 24 hours. The temperature at the bottom in the same time rose to 79° F., or less than 2° per day." At this point the bulk was rebuilt and the temperature of the pile again rose steadily for 5 or 6 days, after which it gradually declined and thermometer readings were discontinued. The product was sold and pronounced to be well sweated by the dealers.

A second bulk consisting of 1,305 lbs. of wrappers was fermented in the same manner. The bulk was rebuilt 3 times. Data for the rise of temperature of the top, center, and bottom of the bulk are given for each of the different periods.

"The [fermented wrapper] leaf was examined by a dealer in leaf tobacco and by a cigar manufacturer, both of whom found it 'well sweated,' not distinguishable from leaf fermented by the usual methods, and having an odor of old tobacco quite different from the leaf which had been fermented at a high temperature in cases.

"These observations indicate that high temperatures, 120-130° F., are not at all necessary for the rapid fermentation of tobacco, and that Connecticut leaf will ferment perfectly well in piles instead of cases, and when the process is complete, will be moist enough to be readily handled and cased down."

Wheat (*Kentucky Sta. Bul. 83, pp. 35-50, pls. 2*).—Variety experiments and fertilizer tests with wheat are reported.

Thirty-three varieties of wheat were grown in 1899. The yields of straw and grain per acre are tabulated for each variety. Field notes on each variety and the meteorology ot the season are given, together with descriptive notes and illustrations of 13 varieties not previously described by the station (E. S. R., 10, p. 842). Kansas Mortgage Lifter gave the largest yield, 14.6 bu. per acre, and the heaviest grain, 66.5 lbs. per bushel, of the varieties grown in 1899, followed by Turkish Red, 13.9 bu.; Fultzo-Mediterranean, 13.2 bu.; Rice wheat, 13.2 bu., and Indiana Swamp, 13 bu. per acre.

The fertilizer experiment at the station gave only negative results, and the results of 2 cooperative experiments were not striking. The experimental land in every case was poor and the net value of the crops on the plats receiving fertilizers in no instance exceeded the value of the crop on the best plats receiving no fertilizers.

Variety tests of wheat, G. C. WATSON and E. H. HESS (*Pennsylvania Sta. Bul. 46, pp. 7*).—Thirty-two varieties were tested in 1898 and 22 in 1899. Average yields of a few varieties for 2, 3, 4, 6, 9, and 10 year periods are also given. The best yields of grain in 1898 were as follows: Dawson Golden Chaff, 41.42 bu.; Gold Coin, 37.97 bu.; Forty-fold, 37.57 bu., and Fulcaster, 37.15 bu. per acre. Wet weather in June caused a weak growth of straw, as a result of which 49.2 per cent of the smooth varieties and 76.5 per cent of the bearded varieties lodged badly. In 1899 the best varieties grown as regards grain yield were: Royal Red Clawson, 26.87 bu.; Forty-fold, 26.8 bu., and Dawson Golden Chaff, 26.43 bu. per acre. Reliable, Fulcaster, and Ontario Wonder, with yields of 31.82, 31.77, and 31 bu. per acre, respectively, have given the best average results for 10 years.

The question as to whether wheat will run out is discussed with the aid of tables. Varieties grown at the station for 10 years show an increase in yield of 0.05 bu. of grain per acre and 1.04 lbs. in weight per bushel for the last 5 years over the preceding 5 years of the test, but a decrease in the yield of straw for the same period of 424 lbs. per acre. In this connection the author notes that, "On the limestone soils of the State where proper cultivation and fertilization are given and due regard had to the selection of the seed, a variety of wheat should not run out. Where the soil, cultivation, manuring, and seed selection are not the best, it will pay a farmer to change his seed occasionally."

Fertilizer tests on winter cereals, L. VAN DEN BERCK (*Belg. Hort. et Agr., 11 (1899), No. 19, pp. 292, 293*).—*Wheat.*—Three plats of 5 acres each of clay soil were employed. The preceding crop had been potatoes fertilized with a light dressing of stable manure. In the test no fertilizers were employed on plat 1. Plat 2 received fertilizers at the rate of 800 kg. of Thomas slag containing 16 per cent of phosphoric acid; plat 3, the same amount of slag and in addition a fractional application of 250 kg. of nitrate of soda per hectare. Plat 1 yielded at the rate of 1,860 kg. of grain and 3,225 kg. of straw per hectare; plat 2, 2,310 kg. of grain and 3,990 kg. of straw; and plat 3, 3,065 kg. of grain and 5,970 kg. of straw. The results are believed to show the value of using nitrogen with phosphoric acid for wheat when the preceding crop has been other than a leguminous one.

Rye.—The experiments with rye were conducted on plats of sandy soil, similar in size to the ones noted above, which had been cropped with potatoes the preceding season. Plat 1, which received no fertilizer, yielded at the rate of 1,720 kg. of grain, and 3,750 kg. of straw per hectare; plat 2, fertilized at the rate of 600 kg. of slag (containing 16 per cent phosphoric acid) and 50 kg. of nitrate of soda, yielded at the rate of 2,220 kg. of grain and 4,100 kg. of straw per hectare; plat 3, fertilized with the same amount of manures as plat 2 in the fall and 150 kg. additional nitrate of soda in the spring, yielded at the rate of 2,640 kg. of grain and 5,060 kg. of straw; plat 4, fertilized the same as plat 3, with the addition of 400 kg. kainit, yielded at the rate of 2,850 kg. of grain and 5,430 kg. of straw. The increased yield due to potash in plat 4 was thought by the author to show the value of using potash on light soils poor in this element.

The wheat crop of 1899, J. B. LAWES (*Gard. Chron., 3. ser., 26 (1899), No. 668, pp. 292, 293*).—The author gives tabulated data showing the yield of wheat at Rothamsted in 1899 on unmanured land and on land fertilized with barnyard manure or commercial fertilizers, and on this basis estimates the quantity which must be imported by the United Kingdom. Wheat grown at Rothamsted successively for 56 years on the same ground yielded in 1899 at the rate of 12 bu. per acre on a plat which has received no fertilizer; at the rate of 42.5 bu. on a plat fertilized with barnyard manure; and at the average rate of 36 bu. per acre on plats receiving commercial fertilizers. Wheat grown on plats in a four-year rotation of roots, barley, clover (or beans), and wheat, in which the whole crop has been removed every year since the beginning of the experiment in 1849, yielded at the rate of 30.25 bu. per acre. Turnips had practically failed on these plats and barley had gradually decreased in yield. These results are interpreted as showing the "remarkable capability of wheat to collect its food from what is, agriculturally speaking, exhausted soil," and as having an important bearing on the problem of future wheat production as related to increasing population.

Utilizing the American corn crop (*Queensland Agr. Jour., 5 (1899), No. 6, pp. 530–532*).—Popular notes on the utilization of corn in the production of oil, spirits, glucose, corn rubber, etc.

Manila hemp (*Sci. Amer., 82 (1900), No 2, p. 24*).—An account of its production in the Philippines and suggestions about machinery needed in its preparation for market.

The sisal hemp, H. J. BOEKEN (*Tropenpflanzen, 4 (1900), No. 1, pp. 6–27, figs. 11*).—Culture and manufacture in Mexico, with descriptions of machinery used.

The manuring of hops, H. H. COUSINS (*Agr. Gaz.* [*London*], *50 (1899), No. 135, pp. 348, 349*).—A summarization is given of a number of experiments with potash salts on hops. The author considers barnyard manure the safest and most satisfactory fertilizer for supplying hops with this element.

Potato experiments, 1898, N. GRAHM (*Tidskr. Landtmän, 20 (1899), No. 14, pp. 242–246*).

Comparison of newly imported potatoes, F. E. H. W. KRICHAUFF (*Jour. Agr. and Ind., South Australia, 3 (1899), No. 5, pp. 449–451*).—Yields and starch content of a number of varieties of potatoes recently imported are given.

Results of fertilizer experiments with potatoes, A. SCHILLING (*Ztschr. Landw. Ver. Hessen, 1899, No. 52, p. 669*).—Data on yield and starch content of potatoes grown on soil fertilized with different amounts and combinations of kainit, superphosphate, chlorid of potassium, and nitrate of soda.

Soy beans (*Kansas Sta. Press Bul. 46, pp. 2; abs. in Bul. North Carolina State Bd. Agr., 20 (1899), No. 11, pp. 26, 27*).—Directions for the culture of soy beans, with an account of the cost of growing and harvesting 60 acres at the station. The total cost was $155.25; total yield, 932 bu.

The Swedish sugar-beet crop of 1898 (*Tidskr. Landtmän, 20 (1899), No. 12, pp. 199–201*).—Area of beets grown, 22,924 hectares; beets delivered to sugar factories, 480,945,500 kg.; average yield per hectare, 20,893 kg. (= 18,644 lbs. per acre); average sugar content, 13.93 per cent.

On the preservation of sugar-beet tops (*Landtmannen, 10 (1899), No. 41, pp. 664–666*).—Sugar-beet tops and beet pulp were buried in pits 3 to 4 meters wide and ¾ to 1 meter deep, in alternate layers, 8 to 12 in. thick; 2 or 3 kg. of common salt were added for every load. When the mass was 3 to 4 ft. high above the ground it was covered with a layer of dirt. The pits were made with flaring wall, and at the bottom a drainpipe was laid to carry off excess of water. The tops and pulp so preserved kept in good condition until the following June. Milch cows ate this silage with the greatest relish, but always ate the beet tops first. An analysis of the ensiled beet tops only was made at Alnarp experiment station laboratory, with results as follows: Water, 83.22 per cent; crude fat, 0.11 per cent; albuminoids, 1.09 per cent; amids, 0.26 per cent; acids (mainly lactic and oxalic), 1.25 per cent; carbohydrates, 5.90 per cent; pure ash, 1.18 per cent; sand (dirt), 6.99 per cent. The silage had no deleterious effect on the quality of the dairy products or on the health of the cows.—F. W. WOLL.

Fertilizer experiments with sugar beets at Alnarp, 1898, H. WINBERG (*Tidskr. Landtmän, 20 (1899), No. 16, pp. 275–277*).

Report on the experiment garden, 1898–99, J. D. KOBUS and J. A. VAN HAASTERT (*Meded. Proefstat. Oost Java, 3. ser., No. 15, pp. 23, dgm. 1*).—Results are given of fertilizer experiments, combined culture and fertilizer experiments, fertilizer experiments with nitrate of soda containing perchlorate, and culture experiments on uplands with sugar cane.

The tillering or stooling proclivities of wheat, J. L. THOMPSON (*Agr. Gaz. New South Wales, 10 (1899), No. 12, pp. 1247, 1248, fig. 1*).—This subject is briefly discussed and an account given of finding 4 stools of wheat containing 112, 120, 120, and 116 straws, respectively, per stool. Thin seeding of cereals to encourage stooling is urged.

Culture experiments with spring wheat, S. RHODIN (*Tidskr. Landtmän, 20 (1899), No. 15, pp. 253–258*).

The treatment and yield of permanent pastures in Switzerland, a report, S. AANESTAD (*Tidsskr.-Norske Landbr., 6 (1899), No. 7, pp. 310–322*).

The irrigation of meadows (*Deut. Landw. Presse, 26 (1899), No. 90, p. 1019*).—A brief discussion of the best time to irrigate grass lands.

HORTICULTURE.

Forcing cucumbers—experiments on the value of deep and shallow benches, O. M. TAYLOR (*Amer. Gard., 20 (1899), No. 259, pp. 830, 831*).—Experiments were made to determine the relative value of growing cucumbers in benches full of soil and in benches containing but little soil, the soil being increased as the plants developed.

Three benches 6 in. deep and 2½ ft. wide, running east and west in an even-span greenhouse, were partitioned and one-half of each filled with a good soil. The other half was filled with the same soil, as required from time to time by the growing plants. On March 15, Improved White Spine, Extra Long White Spine, and Telegraph varieties of cucumbers, which had been started with bottom heat in four-inch pots, were carefully transferred to the benches. The plants were set in 2 rows 2 to 3 ft. apart and 22 in. in the row. Plants in the partially filled benches were filled around with 5 six-inch pots of soil and the soil covered with a thin layer of moss to prevent washing down during watering and spraying. The growing plants were tied to upright stakes, and in the early part of the experiment the laterals were pinched beyond the second pistillate flower. Hand pollination was practiced with the White Spine cucumbers but was omitted with the English variety, Telegraph.

"On April 6, root fibers were showing on the benches with little soil. These were then filled half full and on May 4 the remainder of the soil was added. As early as May 1 it was observed that the growth on all benches containing little soil was not so vigorous nor the foliage so green as on the filled benches, which condition continued until the close of the experiment, on June 22. The benches produced the first marketable fruits and total yield during the experiment as follows:"

Growth of cucumbers in shallow and deep benches.

Variety.	Date of first cut.	Total number cut.
Improved White Spine:		
Shallow bench	May 9	227
Full bench	May 11	212
Extra Long White Spine:		
Shallow bench	May 9	196
Full bench	May 11	210
Telegraph:		
Shallow bench	May 18	113
Full bench	May 23	91

The experiment is thought to indicate that there is "a tendency to earlier maturity and greater yield on shallow benches," and that the blooming period is slightly earlier on the shallow benches. Shallow benches also tend to restrict the growth of the plant. The author suggests that where room is limited for the development of the vines, 9 in. of soil would prove more satisfactory than 6 in.

Report of the assistant in horticulture, A. T. JORDAN (*New Jersey Stas. Rpt. 1898, pp. 127-190, pls. 6*).—The work of the department has been a continuation of that already outlined (E. S. R., 10, p. 433). Experiments with asparagus, blackberries, raspberries, currants, and gooseberries were conducted to study the following problems: The effect of irrigation, the relative effect of fertilizers with and without irrigation, the effect of the addition of nitrate of soda, and the influence of the different treatments upon earliness. The results were as follows:

Asparagus (pp. 130, 131).—Considering all varieties together, irrigation gave in every case the largest first cutting, also the largest totals with a single exception. Among fertilizers the complete fertilizer gave highest yields. Irrigation changed the relative effectiveness of the fertilizers but slightly.

Blackberries (pp. 132, 133).—Irrigation increased the yield at the first picking in 2 cases and the total yield very materially in 3 cases. Irrigation on plats receiving barnyard manure and complete fertilizer gave largest yields. On unirrigated plats, barnyard manure gave largest yields, with ground bone and muriate of potash second. Nitrate of soda gave the smallest yield in almost every case. In point of earliness, ground bone and potash on unirrigated plats, and complete fertilizer on irrigated plats, gave best results.

Raspberries (pp. 133-135).—The results differed but little from those obtained with blackberries. Irrigation did not materially affect the relative effectiveness of fertilizers.

Currants and gooseberries (pp. 135, 136).—In these cases the number of varieties was fewer, and the tests with complete fertilizer were omitted. Irrigation increased the yield in every case with the currants, but with the gooseberries in only one case. On both irrigated and unirrigated plats barnyard manure gave the highest yields.

Strawberries (pp. 136–145).—The lines of experiment reported the preceding year were continued. In tests of fertilizers with and without irrigation, nitrate of soda increased earliness on unirrigated, but decreased it on irrigated plats. The complete fertilizer gave the largest total yield in both cases. The author concludes that "it is inadvisable to apply nitrate of soda in connection with a fertilizer already rich in nitrogen. With low grade materials its addition is beneficial to the crop." Comparative experiments with hill culture and the matted row system were continued, with results confirmatory of those already published.

Variety tests were continued, combined with which were tests of adaptability to hill culture. In only 2 cases did the yield of the hills exceed that of the matted rows.

Variety tests of vegetables have been carried on for 3 seasons, as already outlined (E. S. R., 9, p. 649).

Peas (pp. 146–159).—A comparative test was made of 81 varieties with respect to earliness of starting, earliness of maturing, length of season, percentage of shelled peas in total weight, number of peas per pod and length of same, height of vine, and the yield and weight of same. The smooth sorts are considered inferior to the wrinkled varieties in all respects except earliness. It is believed that all the numerous varieties of dwarf smooth peas are developed from the old Philadelphia Extra Early and Dan O'Rourke, from which they differ but little. Varieties differ much in the yield of shelled peas obtained from a given quantity of pods, an extreme variation of 12 per cent being found. Among the early dwarf wrinkled varieties, Exonian and Station were earliest.

Among the late half-dwarf and tall smooth varieties, Pride of the Market gave nearly twice as large a yield as any other. New Giant Pod Marrow was one of the earliest and most productive of the Marrowfats. Melting Sugar is recommended.

Among the medium and late half-dwarf and tall wrinkled varieties the following are spoken of favorably: Advancer, Admiral, Bliss Abundance, Bliss Everbearing, Yorkshire Hero, Stratagem, Stratagem Improved, Queen, and Héroine. Besides a good yield, the last named gave the largest percentage edible of any variety grown.

Drawings were made of the typical pods of the various sorts, showing the general outline, a cross section, and the split pea. Eighteen of these are published.

A comparative test was made of plants trained to woven-wire trellis and untrained plants, with the result that generally the untrained plants gave a larger percentage of the total yield in first pickings than those trained, but in total yield and weight per plant the trained sorts, with two exceptions, gave much better results than those untrained.

A test of the extent of variation within the same variety was made with duplicates from the same lot of seed and with seed of the same variety from different seedsmen. The test was made on a gravelly loam ridge, sloping mostly to the south, but partly to the north. In the tests of duplicate lots as large differences occurred in all cases on adjacent lots as between plats on opposite sides of the field. The weights per plant varied in the same ratio as did the yields. The extent of variation among lots from different seedsmen was much greater.

A test was made to determine the approximate quantity of seed that should be used per 100 ft. of drill to secure the best results. Five thicknesses of planting were made with 8, 10, 12, 14, and 16 plants per foot of drill, or 1 qt. of seed to 356, 285, 238, 204, and 178 ft. of drill, respectively. In every case there was a greater yield per plant, a larger plant growth, and earlier maturity in the thinnest plantings; but for the space occupied, the thickest plantings gave the largest yield. No difference in the size of pods between the different lots was observable.

Beans (pp. 159–176).—Tests of 72 varieties of beans are reported, and the pods of 14 typical sorts are figured. Tests of extent of variation within the limit of the variety were carried out exactly as with peas. With duplicate lots, similar results were obtained, but with seed from different seedsmen the variation was much greater even than in the case of peas.

In tests made to determine the quantity of seed, sowings were made with 2, 4, 6, 8, and 10 plants per foot of drill, or 1 qt. of seed to 810, 405, 270, 203, and 162 ft. of drill, respectively. "One quart of seed in 162 ft. of drill gave the largest yield. There was a tendency in the thicker plantings toward smaller pods. The vines were more spindling, and general development was reduced in the thickest plantings."

A test was carried on to show that under field conditions a crop of beans and peas followed by sweet corn could be grown during the summer and at the same time the general fertility of the soil be increased by the use of crimson clover. The test was successful with the exception that a not very good catch of clover could be obtained. In connection with the double cropping a test of fertilizers was carried on. Five plats, one twenty-fifth of an acre each, were treated as follows: Plat 1, check; plat 2, barnyard manure, 800 lbs.; plat 3, muriate of potash, 7 lbs., and acid phosphate, 14 lbs.; plat 4, same as plat 3, plus nitrate of soda, 6 lbs.; plat 5, same as plat 3, plus nitrate of soda, 2 lbs., and dried blood, 6 lbs. The results of the test with each vegetable are tabulated. In almost every case barnyard manure gave the largest yields. Plats 4 and 5 of sweet corn gave a poor yield.

In the course of this test ash analyses were made of the different vegetables from each of the plats to determine whether there was any difference in the composition of the vegetables. The results are tabulated, but no deductions are drawn. Food and ash analyses are also tabulated for typical varieties of peas and beans, of pea pods and of the shelled peas, of sweet corn (corn and cob), and of the husks separately.

Bush Lima beans (pp. 177–180).—The author believes that this vegetable has not yet received as much attention as its merits deserve. Tests of 5 varieties are reported.

A test was made to determine the number of plants to be grown in a given space for best results. Earliest maturity, largest yield, and largest plant growth were obtained from plants standing 18 in. apart. For the space occupied, however, the thickest planting (plants 3 in. apart) gave the largest yield.

A comparative test was made of surface and subirrigation, natural conditions, and mulching. The natural conditions gave the best results throughout. A fertilizer test was made with Lima beans, using the same general plan as already described for the peas, beans, and corn. Earliness, yield, and plant development were in the following order: Plats 5, 3, 2, 1. "The quickly available nitrate in plat 4 hastened maturity, while the nitrate in plat 5, as a starter, followed with the more slowly available blood, has given the largest yield."

Tomatoes (pp. 180–190).—Tests of 29 varieties are reported. Perfection, Giant Seedling, Favorite, and Beauty gave the largest total yields.

Nitrate of soda, alone and in connection with potash and acid phosphate, was tested with respect to its effect on earliness. Nitrate of soda applied every 15 days gave the largest yield throughout, and nitrate of soda with minerals produced the earliest and best shaped fruit.

A test was made to determine the best time to sow seed to get the best results considering earliness and total yields. The results were not decidedly in favor of any one date. "Unless one has sufficient space to give plants of the earlier sowings plenty of room for development, the most satisfactory results will be obtained by sowing seed from the 10th to the 15th of March."

A comparison of irrigation, natural conditions, and heavy mulching with salt hay resulted as follows:

> "Irrigation and mulching each increased the amount of rotten fruit, irrigation relatively having the greater increase. The appearance of the fruit from the mulched row was far superior to that of the other rows. The color was also a little lighter. Irrigation increased the [total] yield somewhat, while a very decided increase occurred with mulching. The value of the mulch undoubtedly depends upon the earliness of application and the amount of soil moisture in the ground at the time. Within limits, the earlier the mulch is applied, the better the results obtained."

The relative productiveness of the first plants appearing in a lot of seed and those last or slowest in germinating was compared. The seeds that germinated most quickly gave the largest early and total yields of marketable fruits, amounting in the total to 30 oz. per plant. Not only was the yield of marketable fruit low in the last germinating, but the proportion of culls was considerably greater, there being 28 per cent more culls than in the first germinating lot. It is profitable to select the first plants germinating, discarding all others.

The possibilities of growing 2 horticultural crops, as peas and tomatoes, the same year, and the benefits of lime were tried. Peas were planted early in the spring. Before the crop was gathered, tomato plants were set between the rows. The peavines were left upon the ground after harvesting as a mulch for the tomatoes. The two crops were very successfully grown. In the lime test nitrate of soda in all cases gave the earliest yield, but lime caused a greater growth of vine.

Experiments with shading, B. D. HALSTED (*New Jersey Stas. Rpt. 1898, pp. 337, 338*).—A continuation of work already reported (E. S. R., 10, p. 435). For climatic reasons the growth of spinach was very unsatisfactory, but was evidently favored by shade. Tests were made with lettuce, but no satisfactory results were obtained. Shaded areas of wax and Lima beans yielded much less than fully exposed plants. There was no blight upon either of the areas of wax beans, but the Lima beans were blighted, there being 6 times as much blight on the shaded plants as on those not shaded.

On the plat of Lima beans a test was also made with purslane. This weed was allowed to grow for a short time and was then pulled and weighed. The exposed area produced 18.56 lbs., while the shaded area produced only 2.15 lbs., and this mostly about the edges of the shaded soil where sunlight was most abundant.

Pineapple fertilizers, P. H. ROLFS (*Florida Sta. Bul. 50, pp. 104, pls. 8, figs. 8*).—In this bulletin the general plan, details, and results are given of extensive fertilizer experiments with different forms of potash, nitrogen, and phosphoric acid used alone and in various combinations on pineapples. The effect of the different fertilizers on the general development of the plants, on the leaf area, abundance and earliness of fruit blooms, and on the frost-resisting properties has been studied, and the results are discussed at length and illustrated by diagrams and photographs.

The experiments were carried out on the east coast of Florida on rather poor spruce-pine lands, which had never been fertilized. Fifty-one plats were used, 27 of which were about one-twentieth acre in size and were manured with complete fertilizers. The remaining plats were about $\frac{1}{100}$ acre in size and received incomplete fertilizers. The fertilizer used as a normal formula was made up of 3 per cent nitrogen, 7 per cent potash, and 5 per cent available phosphoric acid. Plats receiving this fertilizer were manured February 7 and 8, 1898, at the rate of 1½ tons per acre, June 27 and 28 with 2½ tons per acre, November 4–12 with 2 tons per acre, April 1–4, 1899, with 1½ tons per acre, and July 6 with 1½ tons per acre. After the first application, a number of the plats were further subdivided into from 3 to 6 sections in order to study the effects of increasing or decreasing the amounts of the different fertilizer elements in the normal formula. The source and composition of the manures used, number of plants in each plat, and the combinations and amounts of fertilizers used on each plat and plat subdivision at the different dates of application are given in detail.

A summarization of the accumulated data shows results as follows: The leaf area development of the plants, found by multiplying the width of the leaf at the base by its length in inches and dividing by 2, was greatest on plats fertilized with a blood, bone, and tankage mixture, an average of 34.6 sq. in. per leaf. Of the potash manures the largest average leaf area was found on plants grown on the plats which had received potassium-magnesium carbonate, 30.8 sq. in. per leaf. The leaf area of plants fertilized with bone meal averaged 32.34 sq. in., while the average of the plants receiving acid phosphate was only 25.2 sq. in. On plats which received nitrogen and phosphoric acid but no potash, the average leaf area was 28 sq. in. per leaf, and on plats which received nitrogen and potash but no phosphoric acid 26.8 sq. in. per leaf.

The frost-resisting properties of the plants were greatest in sections receiving the normal formula, or the normal formula with a double amount of phosphoric acid or potash. Increasing the nitrogen in the normal formula, or increasing the normal formula 1½ or 2 fold caused the plants to be more sensitive to frost. Considering the value of the different forms of nitrogen in the complete fertilizers, the data show that plants fertilized with blood and bone were more frost resistant than plants fertilized with cotton-seed meal, sulphate of ammonia, or nitrate of soda in the order named. With regard to potash, plants fertilized with potassium-magnesium carbonate were more frost resistant than plants which received kainit, muriate of potash, or sulphate of potash (both low and high grade forms). "Plats fertilized with acid phosphate were no more nor less frost-resistant than those fertilized with bone meal." Plants receiving incomplete fertilizers were less frost-resistant than the average of those which received complete fertilizers. "An excess of potash or phosphoric acid does not seem to increase the frost-resistant qualities over the normal formula." No relation was found to exist between the leaf development of the plants on the different plats and their frost-resisting properties, as some of the best developed plants were among those most injured by the February freeze. Nitrate of soda and sulphate of potash both had a tendency to hasten the blooming period and the number of blooms, and at the same time to increase the sensitiveness of the plants to frost. A table of fruit picked on some of the plats during the month of June, 1899, is given.

On the basis of these experiments the author suggests a plan for fertilizing pineapples in Florida as follows: If the plants are set in July or August, a handful of fertilizer composed of 3 parts cotton-seed meal and 1 part fine ground unleached tobacco dust should be immediately dropped into the bud. This serves the double purpose of preventing the plants from filling with sand and of furnishing them with a certain amount of food. In October or early November, an application of 680 lbs. of blood and bone and 500 lbs. of potassium-magnesium carbonate per acre should be applied. This application should be repeated the following February or as soon after as danger of frost is past. If the plants are in good condition, this amount may be increased to 1,000 lbs. of blood and bone and 750 lbs. of potassium-magnesium carbonate. Shortly before the beginning of the rainy season a third application, consisting of 1,000 to 2,000 lbs. of blood and bone, and from 750 to 1,500 lbs. of potassium-magnesium carbonate, should be given. This should be followed by another application in October or early November. Should the plants fail to thrive at any time during the season a light application of nitrate of soda is recommended.

The insects and diseases most affecting pineapples are noted and suggestions offered as to their control.

Tea culture: The experiment in South Carolina, C. U. SHEPARD (*U. S. Dept. Agr., Rpt. No. 61, pp. 27, pls. 9, figs. 1*).—A report on the growing of several varieties of tea at Pinehurst estate in South Carolina, on different soils, with an account of the cost of production, machinery used, and methods of picking and handling employed in the manufacture of tea, and a discussion of the possibility of tea growing in this country.

Experiments begun on a small scale in 1889 have been continued until at the present time [illegible]0 acres are under cultivation. The labor problem has been solved by the establishment of schools where negro children are taught the ordinary school branches free of charge, and also to pick tea leaves under the direction of a competent teacher. The actual cost of pruning, manuring, cultivating, leaf picking, and factory work for a crop of 300 lbs. of Assam-hybrid tea obtained from the garden in 1898 was 28.5 cts. per pound. It is thought this cost might be reduced to 16 cts. per pound on large plantations.

Some of the more important data on the cost, yield, etc., of tea-growing at Pinehurst for a number of years on different soils are shown in the following table:

Production, cost, etc., of tea growing at Pinehurst.

Location.	Variety of plant	Age of garden.	Extent of garden.	Distance between plants.	Production of green leaf in 1898.	Production of dry tea in 1898.	Production of dry tea per plant in 1898.	Cost of commercial manure per lb. of dry tea.[a]
		Years.	*Acres.*	*Feet.*	*Ounces.*	*Pounds.*	*Ounces.*	*Cents.*
Drained pond	Assam hybrid	9	0.83	6	21,701⅛	323	5.57	2.3
Clayey hillside	do	9	1.50	6	12,631⅛	188	1.88	5.3
Sandy level	do	9	.66	6	6,959½	103½	2.57	5.0
Cleared swamp	do	9	2.66	6	22,069	328	1.78	3.9
Do	do	8	1.87	6	16,110	240	1.92	4.1
Mostly clayey hill	Chinese	6	2.00	4	20,653	308	1.00	5.0
Drained pond	Darjeeling	4	1.90	4	17,854	266	1.00	4.0

[a] The fertilizer used contained 5 per cent available phosphoric acid, 5 per cent potash, and 5 per cent ammonia (chiefly from dried fish and blood).

The tea plant requires a moist climate and soil and an abundance of complete fertilizers. The best results at Pinehurst have been obtained on moist, well-drained, level land. The use of cowpeas is advised for planting between the rows.

Tea growing should not be undertaken where the temperature frequently goes lower than 25° F. The freeze of February, 1899, made it necessary to vigorously prune back all the tea plants at the Pinehurst plantation to within a few inches of the ground. The plants were protected in part by a covering of snow. Plants which had been most exposed to the weather and had thus best ripened their wood were least injured. The freeze diminished the early picking of tea slightly, but the total yield in 1899 exceeded that of the previous season by about 23 per cent and no diminution in the strength of the finished tea was observed.

Considerable green tea of excellent quality has been produced. Hand labor was necessary in its preparation and this made its production costly. A well-equipped two-story factory has been built for the manufacture of black tea, with a capacity of 50 lbs. of dry tea per day. A description is given of the factory and equipment. The results thus far obtained seem to make it probable that "the cultivation of tea can be made profitable in the warmer portions of the United States in two ways . . . (1) By establishing a plantation . . . with a capital sufficient to carry the work to a point where the product can be offered on equal terms with teas holding an established place in the markets of the United States, and (2) to grow tea for home use in the farm garden."

The cheaper grades of tea can not be profitably grown without the protection of an import duty of 10 to 20 cts. per pound. The better grades can be grown at a financial profit in the Southern States without fear of serious competition from oriental producers, wherever climate and labor conditions are satisfactory.

Detailed directions for the culture of tea, picking the leaves, handling the crop, etc., are given. It is thought that a few tea plants might be profitably grown in nearly all Southern home gardens and thus furnish a supply of tea for family use. The experiments are being continued and extended.

Experiments in chestnut grafting, W. E. Britton (*Connecticut State Sta. Rpt. 1898, pp. 276–288, pls. 2, figs. 1*).—The results of grafting chestnuts at the station at different dates and by different methods and the experience of 3 prominent Connecticut horticulturists in chestnut grafting are detailed, and notes given on the technique of chestnut grafting, characteristics of American, European, and Japanese chestnut scions, and in making grafting wax. A short bibliography of chestnut literature is appended.

The experiments at the station involved the use of more than 200 scions of the better varieties of European and Japanese chestnuts. These were grafted on American stocks (*Castanea dentata*) at different dates in April, May, and June. Cleft grafting was generally practiced and 2 scions usually placed in each stock. Whip grafting was employed where the stocks were small. Grafting wax was freely used, care being taken to cover each portion of the wound air tight, and the tops of scions when cut. Raffia was used as tying material.

Accidents befell a number of the grafts. The dates of setting the remaining grafts, average growth, and number of grafts living October 1 are shown in the following table:

Results of chestnut grafting at the Connecticut Station in 1898.

Time of setting scions.	Number of scions set.	Alive October 1.		Average growth.
		Number of scions alive.	Percentage of number set.	
				Inches.

After June 15	12	2	17	8

The author states that the scions first set were mostly of the Japanese variety, and that those set the last half of May were set in the tops of large trees, while the others were mostly placed in thrifty young sprouts or seedlings. Most of the stocks when exposed to the sun were severely injured by sun scald, whole branches in some cases dying back to the fork or body of the tree. To avoid this the author thinks it advisable to leave enough branches to afford partial shade to the grafts for some weeks after the scions have been set. Whip or tongue grafts made the smoothest unions.

The experience of A. J. Coe at Meriden, Conn., and others is reported. During the season of 1895–96, some 18 acres of sprout land at Meriden was cleft grafted with Japanese scions. The author visited this orchard in 1897 and, while no accurate census was taken, he considers that about 30 or 35 per cent of the grafts set lived and grew. J. H. Hale reports that out of 600 grafts set in native sprouts 1 to 2 in. in diameter in the spring of 1897, when the leaves were just starting on the stocks, only about 25 per cent of them lived and grew through the season. Both European and Japanese scions were used, and cleft, saddle, and tongue grafting employed. Cleft grafting proved the least successful. Seventy-five per cent of the Japanese variety Reliance lived. N. S. Platt finds the after-care of chestnuts during the first season almost as important as the grafting, and recommends the prompt removal of robber shoots and additional branches. Bud grafting at the surface of the ground and root grafting have been failures with Mr. Platt. With stock ¼ in. in diameter 3 ft. from the ground, Mr. Platt finds it desirable to cleft graft; but with stocks ¾ in. in diameter at this height the bark graft is preferred.

Experiments with lawn grasses, B. D. HALSTED (*New Jersey Stas. Rpt. 1898, pp. 327, 328*).—In 1896, 9 plats were seeded with grass and they have been closely cut with a lawn mower during each season since that time. The author shows in a table the species of grass in each plat and its relative stand for 3 years. Based on the results for 3 years, the author believes that a satisfactory lawn mixture would consist of Rhode Island bent grass, Kentucky blue grass, redtop, and Italian rye grass.

Sketch of the present status of horticulture, gardening, and viticulture in Russia, and the government measures for their development (*St. Petersburg: Min. Agr. and Imp. Domains, 1899, pp. 110; rev. in Selsk. Khoz. i Lyesov., 194 (1899), July, p. 179*).—Prepared for the Russian National Exposition of Horticulture held at St. Petersburg in the fall of 1899.

Composition and application of manures, A. H. BENSON (*Queensland Agr. Jour., 5 (1899), No. 6, pp. 565–574*).—The use of fertilizers with formulas for their application in the growing of citrus fruits, bananas, pineapples, strawberries, and certain other garden and farm crops.

The Chevrier kidney bean, H. DAUTHENAY (*Rev. Hort., 71 (1899), No. 15, pp. 363–365*).—Notes on the care and management of these beans to maintain their color and a brief account of the beneficial use of nitrate of soda in their culture.

Methods of winter preservation of endive and other chicory plants, A. OGER (*Rev. Hort., 71 (1899), No. 24, pp. 569–572, figs. 3*).

Culture and manufacture of ginger (*Rev. Cult. Coloniales, 6 (1900), No. 44, pp. 8–13*).

Instructional fruit stations, E. LUCKHURST (*Jour. Roy. Hort. Soc. [London], 23 (1899), pt. 2, pp. 151–154*).—The ends, aims, and practical uses of these stations are discussed. Experimental areas are limited to half-acre plats.

Fruit culture and geology, HANS REUSCH (*Norsk Havetidende, 15 (1899), No. 10, pp. 158, 159*).

The peach (*Topeka: Kansas State Hort. Soc., 1899, pp. 159, figs. 18, dgm. 1*).—Compiled account of the planting, care, management, gathering, packing, and shipping of peaches, with special reference to Kansas. Directions are given for combating insect and fungus pests, and a diagram shows the number of peach trees in 1898 in each county of the State.

Roofing over orange orchards (*Fruitman's Guide, 8 (1900), No. 208, p. 13*).—Methods and results in California.

Olives and olive oil, P. D'AYGALLIERS (*L'olivier et l'huile d'olive. Paris: J. B. Bailliere & Sons, 1900, pp. 350, figs. 64*).

The pawpaw (*Agr. Mexicano, 8 (1899), No. 6, pp. 189–192*).—The history of this interesting fruit in the tropics and its uses as food and medicine are given.

Coffee culture in Queensland, H. NEWPORT (*Queensland Agr. Jour., 5 (1899), No. 6, pp. 584–587*).—Directions for selecting seed, preparing the soil, planting, etc., with notes on varieties and seed germination.

On coffee, W. L. A. WARNIER (*Rec. Trav. Chim. Pays-Bas, 18 (1899), p. 351; abs. in Bul. Soc. Chim. Paris, 3. ser., 21 (1899), No. 24, p. 1104*).—The results of a large number of analyses of coffee from different sources.

Peaberries and male coffee plants (*Queensland Agr. Jour., 5 (1899), No. 6, pp. 582, 583*).—Poverty of soil and dry weather are said to be the causes which tend to the multiplication of peaberries on coffee trees, and the amount of peaberry on a coffee tree is no indication whatever of the sex of the tree.

Shade trees for coffee plantations, L. PIERRE (*Rev. Cult. Coloniales, 6 (1900), No. 4, pp. 4–8*).

Cacao culture in Ecuador (*Planting Opinion, 4 (1899), No. 51, pp. 1018–1020*).—The extent of the production of cacao in Ecuador, methods of planting, cultivating, gathering, cost of growing, and uses are considered, and a description given of the tree, flowers, and fruit.

The cultivation of cocoanut trees (*Shamba [Zanzibar], 1899, No. 17, pp. 1, 2*).—A yield of 7,250 nuts obtained from 350 trees at one picking is recorded. The large yield is attributed to the good effects of digging up the soil to a radius of 6 ft. around each tree, leaving a ridge at the circumference to catch and retain the water. The area was enlarged a little at each digging.

Rubber—the plants that produce it and their cultivation (*Bol. Agr. Min. e Ind., Mexico, 8 (1899), No. 12, pp. 3–35*).

Amur grapes (Vitis amurensis), Tairov et al. (*Odessa, 1898, pp. 37; rev. in Selsk. Khoz. i Lyesov., 193 (1899), May, p. 466*).

The culture of grapes on sands, V. Bertensou and P. For (*St. Petersburg: Min. Agr. and Imp. Domains, Dept. Agr., 1899, pp. 44; rev. in Selsk. Khoz. i Lyesov., 193 (1899), May, pp. 467, 468*).

Forced culture of table grapes, E. Zacharewicz (*Prog. Agr. et Vit., 16 (1899), No. 53, pp. 766–768, figs. 5*).—Illustrated descriptions of grape houses used in the culture of early table grapes, with notes on the cost of construction.

Irrigation and the quality of wine, L. Degrully (*Prog. Agr. et Vit. (Éd. L'Est), 20 (1899), No. 51, pp. 697–701, fig. 1*).

Rose cultures, W. E. Britton (*Connecticut State Sta. Rpt. 1898, p. 268*).—An account with detailed data of growing Duchesse de Brabant roses in the greenhouse in compost, and in coal ashes and peat moss to which commercial fertilizers had been added. Plants set in coal ashes and peat moss gave larger but somewhat lighter colored blooms than those grown in compost. No difference was noticeable as regards fragrance and form. Plants in both media bloomed freely all winter.

Half a century's experience in ornamental tree planting, O. B. Hadwin (*Boston: Massachusetts Hort. Soc., 1900, folio*).—A paper read by the author before the Massachusetts Horticultural Society, in which an account is given of the author's farm experience in planting different varieties of ornamental trees in Massachusetts.

Lawn-grass mixtures as purchased in the market, compared with a few of the best, W. J. Beal (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 59–63*).—The author has observed and experimented with different lawn grasses for a period of 20 years or more, and gives his observations on the value of various grasses for lawns. He also gives approximately the relative abundance of different kinds of grass in each of 17 mixtures, together with the retail price. Many of these grasses are said not to be adapted to lawn purposes and, so far as his observations go, none of the mixtures in the market produce as fine and permanent a lawn as a few of the best grasses used separately. An additional objection to lawn mixtures is the price, which is frequently 3 or 4 times what it would be if the different varieties were purchased separately.

The propagation of ferns, W. C. Worsdell (*Gardening, 8 (1900), No. 176, pp. 122, 123*).—Methods best adapted for the propagation of different species are discussed.

FORESTRY.

Practical assistance to tree planters, G. Pinchot (*U. S. Dept. Agr., Division of Forestry Circ. 22, pp. 11, figs. 5*).—In line with the cooperative plan already announced (E. S. R., 10, p. 443), the Division of Forestry of this Department is prepared, so far as its limited appropriation will permit, to render practical and personal assistance to farmers and others by cooperating with them to establish forest plantations, wood lots, shelter belts, and wind-breaks. A section of the Division has been recently organized which will devote its entire time to investigations in tree planting and to the assistance of those who may avail themselves of the cooperative plan outlined in this circular.

Notes are given on tree planting in the past, value of forests to farmers, and sketches of various successful forest plantations. A form of agreement between the owner and this Department is given.

The white pine (Pinus strobus), V. M. SPALDING and B. E. FERNOW (*U. S. Dept. Agr., Division of Forestry Bul. 22, pp. 185, pls. 13, figs. 40*).—This bulletin was prepared a number of years ago, but delay in its publication made it possible to revise and extend the manuscript, bringing it up to date. The object of the monograph is to lay the basis for an intelligent recuperation of the virgin growth of the white pine forests by the application of rational sylviculture in the remnants of our pineries.

The geographical distribution of our white pine is given and commented upon. Roughly traced, this tree frequents the region adjacent to the Great Lakes, the St. Lawrence Valley, and eastward to the Atlantic Ocean, extending south along the Appalachian Mountain chain. At present there are not less than 400,000 square miles in the United States and the Dominion of Canada throughout which it is said the successful cultivation of the white pine is assured. There is also evidence to show that within the extreme limits of distribution this species makes under cultivation a healthy and rapid growth, and there is apparently no species of equal value indigenous to eastern North America; that is, adapted to so wide an area. On account of the habits of the species near its western limit, as well as results obtained from experimental planting, it seems that successful growth can not be depended upon much beyond its limits.

A discussion is given of the white pine lumber industry, and the original stand and present supply compared. The visible supply at the end of 1897 is placed at about 15 per cent of the original stand. The natural history, including botanical description, relationships, and morphological characters, is given at some length. The rate of growth in height, diameter, and volume, as determined by a large number of observations, is given. The authors discuss the conditions of the development of the white pine, as well as its yield as a crop.

The dangers and diseases to which the white pine is subject are described, that portion treating of the parasitic diseases being translated largely from Hartig's "Lehrbuch der Baumkrankheiten." A chapter is added by F. H. Chittenden, Division of Entomology of this Department, on "Insect enemies of the white pine," in which a number of species are figured and described.

Suggestions are offered for forest management, both of the natural reproduction and artificial plantings, and a brief review is given of the white pine in Germany, where it has been planted for more than a century, and a statement is made that it will probably become one of the prominent forest trees of that country.

The wood of the white pine, F. Roth (pp. 73–82).—The author gives the results of extensive studies into the character and physical properties of this wood, treating of its specific weight, shrinkage, strength, durability, and uses.

An appendix, giving tables of measurements made in the field by A. Cary and A. K. Mlodziansky, completes the bulletin.

Observations on the denudation of vegetation—a suggested remedy for California, M. MANSON (*Sierra Club Bul., 2 (1899), No. 6, pp. 295–311, pls. 4*).—This is a discussion of the injuries due to the denudation of vegetation, based more particularly on observations in the Caucasus and in the Rocky Mountains and the Sierra Nevada.

"The writer advocates that all forest reservations and public lands upon mountain slopes, within the borders of California, be granted by act of Congress to the University of California in trust; that the object of this trust be to protect, maintain, develop, and extend the water supply of these areas forever. For this purpose, that the regents be empowered to lease, under proper control, the timber cutting and pasturage privileges of these areas, and to use this fund: (1) To protect the catchment areas; (2) to maintain a college of practical forestry; (3) to construct reservoirs at such points as may be necessary to the industries of the State, and dispose of the water for the benefit of the trust; (4) to acquire mountain lands to be added to the catchment areas; and (5) to do all such things as may maintain wise systems of forest and water conservation and use."

Forestry in Bosnia and Herzegovina (*Oesterr. Forst u. Jagdw. Ztg., 17 (1899), No. 39, p. 306*).—Gives some statistics on the extent and production of the forests in the above-mentioned countries.

The organization of experimental forestry work in Russia, V. KLYUCHNIKOV (*Selsk. Khoz. i Lyesov., 194 (1899), Aug., pp. 299–302*).—A criticism of certain proposed measures.

On forestry experiment stations, C. G. G. HOLMERZ (*K. Landt. Akad. Handl. Tidskr., 33 (1899), No. 2, pp. 99–106*).

The forest domain of Belgium (*Bul. Soc. Cent. Forst. Belg., 6 (1899), No. 7, pp. 470–494*).—Contains an abstract of the discussion relative to the budget for the administration of forests, etc.

Notes concerning a few trees in the arboretum at the Michigan Agricultural College, W. J. BEAL (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 87–89*).—The author began planting a small arboretum in 1875, and has investigated more than 150 species of trees and shrubs. Notes have been given from time to time on the growth and behavior of these different plants, and in the present paper a tabulated statement is given of the age, height and diameter of a few of the more promising species. Among those mentioned the locust has proved one of the most profitable trees for growth, followed closely by the chestnut, and also by the white ash, white pine, white oak, shaggy-bark hickory, basswood, and sugar maple, and, for poor sandy lands, Norway pine.

Some timber trees of Queensland, J. W. FAWCETT (*Queensland Agr. Jour., 5 (1899), Nos. 5, pp. 499–502; 6, pp. 591–594*).—Notes are given on *Eucalyptus platyphylla*, *E. tesselaris*, *E. microcorys*, *E. maculata*, *E. botryoides*, *E. resinifera*, and *Tristania suaveolens*. The different species are described and their distribution and uses given.

The pinetum at Wellesley (*Gardening, 7 (1899), No. 162, p. 274*).—Notes are given on the pinetum which was laid out in 1865. A list of more than 100 species and varieties of evergreen trees that have proved hardy in New England is appended, most of the species being conifers.

The cork tree (Quercus suber), N. PIKE (*Sci. Amer. Sup., 47 (1899), No. 1222, pp. 19593, 19594*).—Notes are given on the history, cultivation, and uses of the cork oak.

Notes on the Douglas fir, N. I. CRAHAY (*Jour. Soc. Roy. Agr. Belg., 1899, pp. 138, 153–161*).—Notes on *Pseudotsuga douglasii*.

Height growth in plantations, J. SIMPSON (*Gard. Chron.*, *3. ser.*, *26* (*1899*), *No. 662*, *pp. 187*, *188*).—Discussion of this subject as applied to forestry.

Sheep grazing in Arizona, E. S. GOSNEY (*Forester*, *5* (*1899*), *No. 10*, *pp. 230–232*).—The author defends the claim of the sheepmen that grazing does not seriously injure forests or interfere with irrigation works by causing them to fill with silt, etc.

SEEDS—WEEDS.

Germination tests with onion seeds, E. H. JENKINS (*Connecticut State Sta. Rpt. 1898*, *pp. 313–316*).—A number of experiments have been made with onion seeds to test their vitality as affected by age, crop, and variety. Comparisons were made between the vitality of Connecticut and California grown seeds, from which it appears that the latter possessed a higher percentage of germinative ability than Connecticut-grown seed. The average vitality of Connecticut-grown seeds of the crops from 1894–1898 was tested with the result that the 1898 seed was found to possess an unusually low vitality, the reason for which is unexplained. The germinative capacity of different varieties of onion seed was tested, Yellow Globe, Red Globe, White Globe, White Portugal, and Wethersfield Red being compared. All the varieties possessed essentially the same germinative ability except the White Portugal, which was about 6 per cent below the average of the germination of the other varieties. The tests of the Connecticut-grown seed are given in tabular form.

Crimson clover seed, A. J. PIETERS (*U. S. Dept. Agr.*, *Division of Botany Cir. 18*, *pp. 4*, *fig. 1*).—The increased use of crimson clover as a standard crop has led to inquiries regarding its seed. The seed is described, and in general it is stated that crimson clover seed is less liable to contain weed seed than that of the other clovers. In a number of tests made at the laboratory, however, the seeds of 50 weeds have been found more or less frequently. The most serious adulteration is that of the Egyptian clover (*Trifolium alexandrinum*). The differences between the 2 kinds of seeds are pointed out so that one may be able to recognize admixtures of the less desirable species. Notes are given on the germination of clover seed and the amount of seed required per acre. The seed laboratory also offers to test samples sent for that purpose.

On the presence of hydrocyanic acid in the seeds of Vicia, F. F. BRUIJNING and J. VAN HAARST (*Extr. from Rec. Trav. Chim. Pays-Bas*, *18* (*1899*), *No. 6*, *pp. 168–171*).—The authors have made a study of the seeds of a number of species of Vicia to determine the presence of hydrocyanic acid by the method suggested by Dragendorff. Among the species examined were various varieties of *Vicia sativa*, *V. canadensis*, *V. hirsuta*, *V. angustifolia*, *V. narbonensis*, *V. cracca*, *V. biennis*, *V. disperma*, *V. pannonica*, and *V. cassubica*. Among these the *V. angustifolia* yielded the maximum amount of hydrocyanic acid.

The conclusions of the authors are that most species and varieties of the genus Vicia contain amygdalin or analogous bodies, and that the seeds of certain species possess a considerable quantity of hydrocyanic acid, under certain conditions the amount being sufficient to injure animals. To this fact may be attributed the injurious effect of feeding some species after the seeds have matured.

Some chemical changes in the germination of the seeds of Vicia faba, I. SHULOV (*Izv. Moscow Selsk. Khoz. Inst., 5 (1899), pt. 2, pp. 192-202*).—Seedlings 10 days old were investigated. Of the results obtained by the author the following are the most important: Asparagin is rather uniformly distributed in the various organs, while the other amido compounds show a much higher concentration in the cotyledons than in the stalks. The results obtained by T. Lokot with regard to peas are quoted at length. In the latter plant scarcely any difference was observed in the concentration of asparagin in different parts of the plant, while the concentration of the other amido compounds varied greatly.—P. FIREMAN.

Experiments with weeds, B. D. HALSTED (*New Jersey Stas. Rpt. 1898, pp. 332-334*).—In 1897 the author mixed and sowed broadcast the seeds of 30 species of weeds, the object being to note the different degrees of ability to maintain themselves against one another. Only about two-thirds of the different species of seed germinated. By midsummer 15 species were well represented. The more or less conspicuous were sunflower, thorn apple, ragweed, ketmia (*Hibiscus trionum*), pigweed, lady's thumb, velvet leaf, chickweed, catchfly, mallow, purslane, wild carrot, shepherd's purse, and Mexican tea (*Chenopodium ambrosioides*). By the end of the season a number of these had disappeared. The following year the sunflower failed to appear and its place was taken by *Mollugo verticillata*, and *Chenopodium album* had become more abundant than *C. ambrosioides*. During the season covered by the report, 28 species have been observed on the plat in numbers ranging from several hundred specimens down to only one or two. Among the troublesome weeds noted, mention is made of crab grass, but this is kept in check to a considerable degree by a smut fungus (*Ustilago rabenhorstiana*), affected plants rarely if ever producing seed.

Noxious weeds of Wisconsin, E. S. GOFF (*Wisconsin Sta. Bul. 76, pp. 53, figs. 39*).—The author gives the text of the amended Wisconsin weed law, in order that farmers throughout the State may have it in a convenient shape for reference. In order to assist as far as possible in destroying the weeds proscribed by law and also other noxious weeds, descriptions are given, and the best methods of eradication suggested for the following weeds: Canada thistle, burdock, white or ox-eye daisy, snapdragon or toadflax, cocklebur or clotbur, sow thistle, sour dock, wild mustard, wild parsnip, Russian thistle, quack grass, wild carrot, chicory, bindweed or morning-glory, horse nettle, buffalo bur, prickly lettuce, and long-leaved plantain.

Report of Stockholm Seed Control Station, 1897–98, O. STJERNQUIST (*Tidn. Stockh. Läns Hushållnings-sällsk., 1899, May, pp. 99–112; June, pp. 130–135; July, pp. 149–156, figs. 6*).—Illustrations are given of a number of new forms of apparatus constructed by the author for seed examination.

Report of the seed testing at the Modena Experiment Station during the year 1898, F. TODARO (*Staz. Sper. Agr. Ital., 32 (1899), No. 3, pp. 257–273*).—Detailed reports are given of the results of tests of some 590 lots of seeds of all kinds, together with special investigations for dodder in clover and alfalfa seed.

Tests of the vitality of vegetable seeds, E. H. JENKINS (*Connecticut State Sta. Rpt. 1898, pp. 310–313*).—Since November, 1897, 333 samples of seeds have been examined as to their vitality. This has been done in the interests of seed growers and seed dealers in the State. The methods of testing were those adopted by the Association of American Agricultural Colleges and Experiment Stations (E. S. R., 9, p. 143). The results of the tests are tabulated, in which the age of the seed as reported, number of samples, and maximum, minimum, and average of germinations are given.

On the absorption of nutrient solutions by wheat and their influence on germination, VINCENT (*Ann. Sci. Agron., 1898, II, No. 2, pp. 272–302*).

The American Cuscuta, E. SCHRIBAUX (*Jour. Agr. Prat., 1899, II, No. 38, pp. 418, 419, pl. 1*).—The author figures and describes *Cuscuta gronovii*. On account of the fact that this species is said to be parasitic upon a number of plants, the author thinks that there is danger from its introduction into fields of forage plants.

On the destruction of Cuscuta by fire, JAURAND (*Jour. Agr. Prat., 1899, II, No. 38, pp. 423, 424*).—The author recommends the covering of affected regions in alfalfa fields with straw or other litter and burning in the early autumn. In this way he claims to be able to rid fields of this parasite without serious injury to the crop.

Destruction of Cuscuta by copper sulphate, A. BRANDIN (*Jour. Agr. Prat., 1899, II, No. 36, pp. 335, 336*).

Nut grass (*Jour. Agr. and Ind., South Australia, 3 (1899), No. 5, pp. 428–430, pl. 1*).—Illustrated notes are given of *Cyperus rotundus*, which is said to have been introduced into New South Wales and Queensland with importations of dahlia roots. Directions are given for the eradication of this pest. The one most advised is the repeated cutting and removing of the plants.

DISEASES OF PLANTS.

Report of the botanist, B. D. HALSTED (*New Jersey Stas. Rpt. 1898, pp. 291–370, figs. 21*).—As in previous years, the principal lines of experimentation in the field have been with truck crops. Spraying experiments have also been continued, in which Bordeaux mixture, ammoniacal copper carbonate, soda Bordeaux mixture, and creolin were tested. Greenhouse investigations have been continued upon a number of plants, prominent among them being roses and violets. Notes are given on the pear blight, which is being studied in an orchard that has been placed at the disposal of the station for a period of 5 years. Studies on weeds and weed seeds have been continued (see p. 749), and numerous additions to the herbarium are reported.

Experiments with turnips (pp. 292–299).—In continuation of the former experiments (E. S. R., 10, p. 443) the study of club root was pursued. During the season covered by the report the ninth and tenth crops on the same land were grown, and the soil had become thoroughly infested with *Plasmodiophora brassicæ*. Gas lime, carbonate of lime, sulphur, and corrosive sublimate were tested. On both the first and second crops sulphur and corrosive sublimate were without any especial effect, while the limed plats were almost without trace of club root. Leaf spot and heart rot were noticeable, but no difference in susceptibility as to variety was noticed.

Experiments with potatoes (pp. 299–309).—Experiments on the repression of potato scab have been repeated for 5 years (E. S. R., 10, p. 444), in which a number of substances have been tested, both as soil treatments and when applied to the tuber. In 1898 sulphur, potassium sulphid, creolin, and corrosive sublimate were compared. From the yield of the different plats the lowest percentage of scab was obtained where sulphur was applied. Lime tended to increase the liability to injury, while corrosive sublimate applications are said to have been without apparent benefit. In another series of experiments potassium sulphid, potassium sulphate, ammonium sulphate, and creolin were added to the fungicides tested in previous years, but the wet season interfered to such a degree that fully 40 per cent of the tubers rotted in the ground. Where corrosive sublimate had been used only 3 out of 63 plants were lacking at harvest. In this experiment, as previously, sulphur gave the greatest freedom from scab, followed by potassium sulphid, the other substances seeming to have been without effect.

An experiment is reported on the value of different parts of a tuber for seed, in which the stem, middle, and bud ends were compared. No material difference was noticed in yield that could be attributed to the different pieces.

Experiments with beans (pp. 309–313).—Experiments with beans have been continued, the ninth and tenth crops being reported upon at this time. Neither the pod spot fungus nor bacteriosis was abundant during the year. Spraying experiments were conducted, from which the yields obtained were to the advantage of Bordeaux mixture, followed by soda Bordeaux mixture. Creolin and ammoniacal copper carbonate were without effect, the yield from the plats sprayed with these substances being less than that obtained from the check. In another series of experiments ammoniacal copper carbonate as a fungicide gave results next in order to Bordeaux mixture. On one plat of new land which had received a dressing of soil from old bean land, a yield equal to the best obtained where fungicides were used, is recorded.

Experiments with sweet corn (pp. 313, 314).—Five varieties of sweet corn were planted in various plats. One, First of-All, was found to be very susceptible to the bacterial disease due to *Pseudomonas stewarti*, as well as to corn smut. At harvest it was found that cross fertilization had taken place between the different varieties to a considerable extent.

Experiments with peas (pp. 314–316).—Soil treatments with sulphur, corrosive sublimate, carbonate of lime, and copper sulphate were tested for the prevention of stem blight. With the exception of sulphur, all the fungicides tended to repress the disease. On the second crop of peas, mildew (*Erysiphe martii*) was quite abundant but did not materially injure the crop. Vines sprayed with Bordeaux mixture had less mildew than the others, but the stem blight was not lessened to any extent.

Experiments with tomatoes (pp. 316, 317).—Where tomato vines were sprayed with Bordeaux mixture, the blight (*Cladosporium fulvum*) was reduced and the yield of fruit increased. Soda-Bordeaux mixture and creolin were less efficient Tomato plants grown upon new lands suffered more from blight than those upon soil which had previously grown tomatoes. Comparisons are also given upon the relative yield, date of ripening, etc., of a number of varieties.

Miscellaneous experiments with vegetables (pp. 318–334).—Notes are given on experiments with Lima beans, onions, spinach, eggplant, lettuce, cucumbers, beets, and celery. In Lima beans there was little disease, and where Bordeaux mixture and soda-Bordeaux mixture were employed no spotted pods were seen. Inoculation experiments with onion smut (*Urocystis cepulæ*) were tried, in which contaminated soil was introduced into rows without effect. Fungicides and shading were tested with spinach. No blight appeared on any plats during the season. Shaded plants were found to be more vigorous than those grown in the open. In experiments with eggplants, 5 times as many sound fruits were obtained from plants grown on new ground as on old ground, and the decayed fruits were 16 per cent on new ground and 61 per cent on old ground. Different degrees of susceptibility to leaf blight (*Septoria lactucæ*) were observed in a number of varieties of lettuce. Nitrate of soda applied to the plats was without effect on the fungus or growth of the plant. In experiments conducted for combating cucumber anthracnose, Bordeaux mixture and soda Bordeaux mixture proved quite efficient. Experiments with beets were conducted to test the value of fungicides for controlling leaf spot (*Cercospora beticola*). But little disease was noticed where the plants had been sprayed with Bordeaux mixture or soda-Bordeaux mixture, while the attack on the other plats was not severe. In experiments with celery but little difference was observed on the shaded plats or where open culture was given and no difference in liability to fungus attack was observed.

Experiments with ornamentals (pp. 324–327).—Observations are given on some diseases, and methods of combating them, of violets, China asters, pinks, nasturtiums, mignonette, phlox, gladiolus, cannas, dahlias, ampelopsis, hibiscus, hollyhocks, Japanese redbud, peonies, and chrysanthemums.

Experiments with trees (pp. 334, 335).—A brief report is given of experiments with young chestnut trees. While in the nursery they were badly attacked by the fungus *Marsonia ochroleuca*. After transplanting and spraying 5 times with Bordeaux mixture they presented a much better appearance. The fungicides, however, seemed to burn the foliage to some extent. Similar treatment with hard maple seedlings was without effect in checking an unknown blight. Horse chestnut trees badly attacked by *Phyllosticta sphæropsoidea* were successfully sprayed with Bordeaux mixture, the sprayed trees being much healthier in appearance than those not so treated.

Experiments with fungicides (pp. 335, 336).—Formulas and methods of preparation are given for the fungicides referred to above.

Experiments with shading (pp. 337, 338).—The results of these experiments have already been referred to under the different crops and are noted elsewhere. (See p. 752.)

Experiments on old and new land (pp. 338–340).—These experiments have been referred to above. Gains were noted in the yield of wax beans, turnips, eggplants, peas, and tomatoes when grown on new land, and losses for tomatoes and cucumbers.

Notes on pea and bean root tubercles (pp. 340–343).—Experiments are reported in which the effect of soil inoculation of peas is shown. Peas were planted upon soil where no leguminous plants had grown for at least 8 years. Portions of the plat received a dressing of soil that had recently borne peas. At harvest 10 plants were taken at random from the treated and untreated plats and the tubercles counted, the result being that there were nearly 10 times as many tubercles on the roots of treated vines as on the untreated vines. The presence of root tubercles on plants from the untreated plats is said to indicate a prolonged vitality of the germs. Observations made upon the second crop showed an almost total absence of tubercles, due doubtless to the different conditions of temperature or the presence of sufficient combined nitrogen. Differences are also noted between the tubercles occurring on the roots of beans and peas.

Experiments with asparagus rust (pp. 343–348).—A bulletin has been issued by the station on this subject (E. S. R., 10, p. 650), in which the information here given is reported.

Experiments with sweet potatoes (pp. 348–351).—In continuation of previous investigations (E. S. R., 10, p. 449) the method of applying sulphur and kainit was studied, from which it was ascertained that sulphur will check soil rot while kainit also has a beneficial influence. It is claimed that when these fungicides are sown broadcast at the rate of 300 or 400 pounds per acre, a good crop of sweet potatoes may be grown on badly contaminated soil.

Experiments with pear blight (pp. 352–354).—A progress report is made on an investigation of this disease (E. S. R., 10, p. 449). While no very definite results have been obtained, summer-pruned trees gave the better yield in the pruning experiments, and in the culture experiments the well-cultivated trees receiving barnyard manure gave the largest returns.

Experiments with peach-root galls (pp. 354–357).—Negative results were obtained in experiments conducted to test soil conditions as related to root knot. Similar results were obtained in experiments where fungicides were added to the soils, no galls having appeared on any of the check plants.

The forcing of peaches (pp. 357–359).—The author notes the premature ripening of peaches in a number of localities, which is thought to be due probably to the cause which produces what is known as peach yellows (E. S. R., 3, p. 485).

Fungi as related to weather (pp. 359–370).—The substance of this article was presented before the Section of Horticulture and Botany of the Association of American Agricultural Colleges and Experimental Stations at its twelfth annual meeting.[1] In general it is shown that severe attacks of a large number of fungus diseases may be expected in seasons having a relatively high humidity.

Mildew of Lima beans, W. C. STURGIS (*Connecticut State Sta. Rpt. 1898, pp. 236–241*).—In continuation of a report on the disease of Lima beans, published by the station in 1897 (E. S. R., 10, p. 296), cooperative experiments have been conducted, in which it was sought to test the difference between thick and thin planting and upright and slanting poles, as regards the prevalence of mildew.

From the results tabulated there appears to be no difference whatever due to the position of the poles, and the difference in stand did not seem to materially affect the presence of the disease. It is stated that experimental rows ran in such a way that the soil at one end of every row was decidedly more moist than at the other. If this had been foreseen the rows would have been run in a different direction, so that there would not have been a possibility of infection at the lower end of each row.

The investigations do not warrant any conclusions, but serve to emphasize the importance of selecting high, well-drained land for the culture of Lima beans, and indicate that wet soil tends to induce the spread of mildew to a degree which no cultural methods will wholly counteract.

Some common diseases of melons, W. C. STURGIS (*Connecticut State Sta. Rpt. 1898, pp. 225–235*).—It is stated that the growing of melons in southern Connecticut for several years has been attended with very discouraging results owing to the attack of a number of diseases, which led the author to make an investigation as to the nature of the trouble and possible means of prevention.

The first disease considered is that which has been previously described by E. F. Smith, of this Department, as the bacterial wilt of melons.[2] This disease is said to be caused by *Bacillus tracheiphilus*. The author describes the disease at considerable length and finds associated with it, as previously suggested, a species of Fusarium to which part of the wilt disease is probably due.

---

[1] U. S. Dept. Agr., Office of Experiment Stations Bul. 65; also E. S. R., 10, p. 712.

[2] The original publication and description of this disease was given in Centbl. Bakt. u. Par., 2. Abt., 1 (1895), No. 9–10, pp. 364–374.

The second disease, which has been under consideration for several years, causes serious injuries to muskmelons. It is a black mold occurring in circular patches on the leaves and is known as *Alternaria brassicæ nigrescens*. This fungus was previously noted (E. S. R., 8, p. 411).

The third trouble seems to be a physiological one and follows the sudden disturbance of the equilibrium between water absorption and evaporation.

Experiments for the prevention of these different diseases were conducted with Bordeaux mixture, potassium sulphid, sulphur, and laurel green, the latter a combined fungicide and insecticide said to contain 10 per cent of copper and 3.75 per cent of arsenic. The application of sulphur to the leaves of melons is not to be recommended. Although it has some value as a fungicide, it tends to seriously burn the leaves. The susceptibility to the bacterial wilt seemed to be unaffected by the presence of fungicides. Dilute Bordeaux mixture and potassium sulphid are both regarded as efficient preventives for the blotching of melon leaves by the fungus Alternaria. The results obtained with laurel green used as a fungicide were unfavorable, and the author does not feel warranted to recommend its use. For the prevention of the physiological trouble of which mention has been made, the author recommends that when melons are grown upon loose sandy soil, it is advisable to apply fertilizers in small amounts at intervals throughout the season or until the spread of the vines makes tillage no longer practicable. In this way the vigor of the vines may be maintained, and they will be more resistant not only to disturbance in the physiological equilibrium, but to fungus attacks likewise.

Preliminary notes on two diseases of tobacco, W. C. STURGIS (*Connecticut State Sta. Rpt. 1898, pp. 212–260*).—Notes are given on the so-called "calico" or "mottled top" of tobacco, and a second disease called "spotting" of tobacco. The calico or mottled top, which the author considers different phases of the same disease, is very common in certain portions of the tobacco regions of Connecticut. The characteristics of the diseases are pointed out, the calico being characterized by a mottled appearance of the leaves, at first almost imperceptible, but soon spreading in blotches all over the leaf surface, the contrasted shades of green being very noticeable. The effect of soil conditions on this disease was investigated, and it was found most abundant in the close clay soils on the east side of the Connecticut River and more sparingly in other localities. Varieties and methods of culture were investigated without obtaining any definite conclusions. The application of fertilizers to the tobacco fields was studied, and it was found that where barnyard manures were extensively used disease was usually present, while where chemical fertilizers were used almost exclusively there was little disease. This does not warrant the statement, however, that the fertilizer is responsible for the presence or absence of the disease, since exceptions are noted where applications of both kinds of fertilizer had been made.

Experiments were conducted in which seeds from badly diseased plants were collected and grown in a hotbed, with the result that of 100 seedlings not one showed a trace of disease. This seems to indicate that the disease is not contagious, and as yet no direct information is known as to its infectiousness. As far as the author has been able to ascertain, it is not caused by insects, nematodes, or parasitic fungi, nor have bacteria been observed associated with it. He seems to think that the disease is a physiological one, caused primarily by sudden changes of atmospheric conditions disturbing the normal balance between evaporation of water from the leaves and its absorption by the roots, and secondarily by soil conditions which prevent the speedy restoration of that balance.

The spotting of tobacco is briefly described and it is said that when present to but a limited extent it results in giving the leaves an increased market value, but when badly affected, the tissues of the leaves are completely destroyed.

Notes are given on investigations of the mosaic disease and a spot disease which have been studied to a considerable extent by investigators abroad. In view of the possible identity of some of these diseases, it is deemed best to record such facts regarding them as experiments may show without generalizing from the rather uncertain character ot the evidence presented.

A bacterial disease of the sugar beet, CLARA A. CUNNINGHAM (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 111-143*).—The author describes a disease of the sugar beet which appears to be not at all rare, at least in Indiana. The whole beet plant is attacked so that the diseased beets can be readily distinguished in the field. The outer and older leaves die early and the younger heart leaves become wrinkled, curled, and of a yellowish-green color. The root of a diseased beet shows no exterior indications of the disease, but when cut open striking differences are noticed in the appearance of the fibrous rings. The diseased root shows dark rings, quite different from the cream-colored ones of the healthy beet. When exposed to the air they become darker, sometimes becoming black after a few minutes.

Numerous cultures upon gelatin and agar have been made which seem to indicate that the trouble is due to bacteria. The behavior of the organism on the media is shown, and associated with it was a second germ that seemed to have nothing to do with the disease in question. The organism which is considered as the cause of the disease is a small, colorless bacillus, measuring 0.9 to 1.3μ in length, by from 0.5 to 0.8μ in breadth. In the beet tissue it is usually quiescent, but in cultures is motile. It is readily stained, but the presence or absence of flagella was not demonstrated. In most culture media an abundance of gas is formed which is shown to be composed of carbon dioxid, oxygen, hydrogen, and nitrogen, the last being 10 per cent or more of the total amount formed. Inoculations of healthy beets in the field and greenhouse appeared to transmit and set up the disease, although the results were not entirely conclusive.

The shot-hole effect on the foliage of the genus Prunus, B. M. DUGGAR (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 64-69*).—The author calls attention to the shot-hole effect produced by a number of different fungi which attack leaves. A list is given of 12 species of fungi all of which produce a shot-hole effect on different species of Prunus, and 2 others are mentioned which do not cause this distinctive marking. From the number of species producing this effect the author was led to believe that it was the result of the reaction of the injury on the part of the host plant. Spraying experiments were conducted with quite a number of chemicals, among them formalin, picric acid, corrosive sublimate, and improperly-made fungicides, in all of which similar results were obtained. From these experiments and from other observations the author states that it is evident that the shot-hole effect of plums, peaches, cherries, etc., is a peculiar reaction of the plant to injuries such as may be produced by many fungi, by certain chemical reagents, and possibly by other causes. These injuries assume an economic importance not only from the point of view of fungus attacks, but also suggest special care in the application of copper compounds to the foliage of susceptible varieties.

Miscellaneous notes on plant diseases and spraying, W. C. STURGIS (*Connecticut State Sta. Rpt. 1898, pp. 261-267*).—Notes are given on *Monilia fructigena* on the peach, bacterial blight of Lima beans, damping-off of peas, relation between plant diseases and weather, a convenient method of preparing Bordeaux mixture in small quantities, and on some forms of spraying apparatus.

During 1898 an attack of unusual severity of Monilia on the peach was noted. In addition to peaches it was also abundant on the ornamental shrub known as the double-flowering almond. After destroying the blossoms, the fungus worked upon the twigs, killing the tissues and causing the leaves to wither. During the fruiting season another attack was noticed, the disease spreading widely and in conjunction with the scab fungus causing a very serious loss in the peach crop. It was thought that pruning and spraying the trees would probably have prevented the loss to a great extent.

A bacterial blight of Lima beans, due to *Bacillus phaseoli* (E. S. R., 9, p. 1058), is briefly described. Based on previous investigations it is thought that 2 sprayings, on July 15 and August 15, would probably have decidedly lessened the injury caused by it.

The damping-off of peas, which ordinarily does not cause serious damage in the open, is said to have greatly injured garden peas, in one locality to such an extent that it was a difficult matter to secure a crop. This disease, which is due to *Artotrogus* (*Pythium*) *debaryanus*, is briefly described, and it is suggested that thin planting and the use of chemical fertilizers, would greatly lessen the liability to loss.

The author discusses the relationship between weather and plant diseases, commenting upon the prevalence of disease in a wet autumn following a dry summer. A method is given for preparing Bordeaux mixture in 5-gallon quantities from previously prepared materials which, in the way suggested, may be kept for an indefinite time.

Notes are given on a number of forms of spraying apparatus which were tested at the station during the past season. The principle upon which the barrel pumps work has been previously described by this station (E. S. R., 10, p. 60). A form of spraying apparatus to be used with pails with a detachable kerosene tank is described at some length. It is stated that the tank can be removed and the aperture closed, after which it may be used for spraying fungicides, and it is well adapted for spraying plants on a small scale.

Rusts of horticultural plants, B. D. HALSTED (*Florists' Exchange, 13 (1900), No. 3, p. 60*).—A lecture before the Massachusetts Horticultural Society.

On the white rust of horse-radish and black salsify, WEISS (*Prakt. Bl. Pflanzenschutz, 2 (1989), No. 7, pp. 51, 52*).

On the prevention of apple scab, A. VON DER PLANITZ (*Prak. Ratgeber Obst u. Gartenbau, 1899, No. 30, p. 265*).

The canker fungus (*Bd. Agr. [London], Leaflet No. 56, pp. 7, figs. 2*).—Notes are given on *Nectria ditissima*, which causes what is known as canker on apple trees. A description and life history of the fungus is given and methods for its prevention described. Young trees should be examined for any signs of canker and infected parts cut out with a sharp knife or, where possible, branches should be cut away. A strong solution of copper sulphate applied in the late autumn or winter is also recommended. Apple trees should be kept free from the apple aphis, as these insects convey the spores from tree to tree. A number of diseases are described which are sometimes mistaken for canker, one of the most common being the fire blight due to *Bacillus amylovorus*.

Notes on a gum flow in fruit trees, C. JOKISCH (*Mitt. K. Gartenbau Gesell. Steiermark, 1899, No. 7–8, pp. 138, 139*).

Fungus parasitic diseases of the grapevine, A. A. YACHEVSKI (*St. Petersburg: Min. Agr. and Imp. Domains, 1899, pp. 2–83; rev. in Selsk. Khoz. i Lyesov., 194 (1899), July, p. 180*).

Recent investigations on black rot, A. PRUNET (*Rev. Vit., 1899, Nos. 292, pp. 110–115; 293, pp. 135–140*).

The occurrence of black rot on grapes, J. CAPUS (*Prog. Agr. et Vit. (Éd. L'Est), 21 (1900), No. 2, pp. 53–56*).—The author points out the relationship between the appearance of the black-rot fungus on grapes and the time of its occurrence on the leaves. The second invasion of the fungus on the leaves produces the first attack on the fruit, etc. It is believed that the most favorable time for applying the fungicides for this disease is prior to the first attack on the leaves, although applications should be made later in the season.

Results of experiments in combating black rot, G. DUFFOURC-BAZIN (*Prog. Agr. et Vit. (Éd. L'Est), 20 (1899), No. 39, pp. 357–360*).—Bordeaux mixture, copper sulphate, and Bordeaux mixture containing mercury were tested, 5 applications being given to the vines. The time of appearance of the different attacks of the fungus are given. The author states that the experiments show that absolute prevention of black rot is possible. In the vineyards covering 15 hectares where the fungicides were employed no trace of black rot was found, while in the checks there was not a sound leaf or grape at the end of the season.

Experiments in treating black rot in 1899 in Haute-Garonne and Bas-Armagnac, J. B. SENDERENS (*Prog. Agr. et Vit.* (*Éd. L'Est*), *20* (*1899*), *No. 44*, *pp. 501–511*).—A report is given of experiments conducted in a number of vineyards with 24 fungicides of different composition or strength for the prevention of black rot. The best results were obtained with a mixture composed of copper sulphate, soda carbonate, and water, containing 2 kg. of copper per 100 liters.

Fungus diseases resembling black rot, V. DUCOMET (*Prog. Agr. et Vit.* (*Éd. L'Est*), *20* (*1899*), *No. 36*, *pp. 276–285*, *pl. 1*).—The author describes a number of diseases of plants which bear a superficial resemblance to the black rot on the leaves of the grape. Among those described are leaf spots of various rosaceous plants, leaf spots of sycamore, parsley, pear, orange, violets, and strawberries. The fungi causing these different diseases are described, the time of their principal attack mentioned, and suggestions given for the prevention of the disease.

Ear cockle (*Jour. Agr. and Ind.*, *South Australia*, *3* (*1899*), *No. 5*, *pp. 431*, *432*, *fig. 1*).—A description is given of the attack of *Tylenchus scandens* on wheat. As a suggestion for the prevention of the spread of this pest it is recommended that all diseased grain be separated by floating in water prior to seeding.

A sugar-cane pest in Madras, C. BENSON (*Dept. Land Records and Agr.*, *Madras*, *Vol. II*, *Bul. 36*, *pp. 113–133*).—Notes are given on the cane disease caused by attacks of *Trichosphæria sacchari*. The symptoms of the disease and methods by which it is spread are described. It is stated that in Madras the method of rotation is such that the ground is practically in sugar cane continuously. Investigations have been made and the disease has been found present in every district in which sugar cane is cultivated to any considerable extent. The life history of the fungus is described at considerable length, as well as numerous fungi which are more or less related to it.

Concerning a bacteriosis of Dactylis glomerata, E. RATHAY (*Sep. Sitzber. Math. Naturw. Cl. K. Akad. Wiss.* [*Vienna*], *108* (*1899*), *I*, *pp. 6*).

On the best time for the treatment of Oidium, A. LAURENT (*Prog. Agr. et Vit.* (*Éd. L'Est*), *20* (*1899*), *No. 46*, *pp. 252*, *253*).—The author states that 2 applications of sulphur in April and May and 1 during June, July, and August are sufficient for preventing attacks of mildew under ordinary conditions.

Recent observations on combating Peronospora and Oidium, E. MAYER (*Ber. Verhandl. 17 Deut. Weinbaukongress*, *Mainz*, *1899*, *pp. 58–74*).

The peronospora of beets, P. VOGLINS (*Extr. Ann. R. Accad. Agr. Torino*, *42* (*1899*), *pp. 11*, *pl. 1*).—Gives description and notes on *Peronospora schachtii*.

A disease of sycamores in the Luxemburg gardens, A. GIRARD (*Compt. Rend. Soc. Biol. Paris*, *11. ser.*, *1* (*1899*), *No. 23*, *pp. 565*, *566*).—Notes are given on *Glœosporium nervisequum*.

The red rot of spruce, C. BOMMER (*Bul. Soc. Cent. Forst. Belg.*, *6* (*1899*), *No. 8*, *pp. 553–567*).

A new disease of azaleas, J. VOGLINO (*Malpighia*, *13* (*1899*), *pp. 73–86*; *abs. in Bot. Centbl.*, *80* (*1899*), *No. 8*, *pp. 313*, *314*).—Notes a very destructive disease due to *Septoria azaleæ*, which is described as new.

ENTOMOLOGY.

Report of the government entomologist for the year 1898, C. P. LOUNSBURY (*Dept. Agr.*, *Cape Good Hope*, *1899*, *pp. 64*, *pls. 9*).—In this report the author has summarized the work of the government entomologist, and gives an account of the assistance which the government is rendering in the way of combating injurious insects. Some progress is reported of cooperation of private individuals with the government for this purpose. In Cape Colony fumigation by means of hydrocyanic-acid gas has been carried on largely by certain companies which have undertaken the work. The extent of such fumigation is steadily being increased and good results have been reported. The entomologist has devoted some attention to the collection and distribution of vedalia. Numerous packages of this insect have been prepared and sent to various addresses. An attempt was made to introduce from Ceylon specimens of *Chilocorus circumdatus*, but without success. A similar unsuccessful attempt was made at introducing *Orcus chalybeus* from New South Wales. The office succeeded in sending live specimens of *Exochomus nigromaculatus* to Ceylon and to New South Wales. The practicability of introducing hymenopterous parasites of scale insects is discussed, as well as the question of importing fungus diseases of these insects.

Biological and economic notes are given on a large number of insects which proved injurious during the season. Among these injurious insects various scales occupy a prominent place. Besides scales we may mention the following as especially injurious: Codling moth, fruit fly (*Ceratitis capitata*), *Phlyctinus callosus*, species of ticks, the woolly aphis, the cabbage plutella, the bollworm, the quince borer (*Cossus tristis*), and species of locusts. The majority of these insects are figured and a general index is appended to the report.

Report of the entomologist, J. B. SMITH (*New Jersey Stas. Rpt. 1898, pp. 373-467, figs. 15*).—In the general part of the report the author gives an account of his experiences during the year with a large number of miscellaneous insects which proved more or less injurious.

The author purchased a plat of land on which were set out 50 fruit trees, most of them being infested with the San José scale, and 2 rows of currant bushes, also infested. This orchard was treated during the year in the way in which the author believes the ordinary fruit culturist treats his own fruit trees. Experiments were tried with a number of insecticides for the destruction of the San José scale, among them pure kerosene, crude oil, and a mechanical mixture of kerosene and water, and whale-oil soap. The crude oil and even the kerosene were found not to cause serious damage to the trees when applied with care. Detailed notes are given of the appearance and behavior of each tree during the whole experiment.

A dwarf Duchess pear badly infested with San José scale was thoroughly painted with crude petroleum from the topmost bud to the surface of the ground. The color of the bark was changed and the tree appeared to be seriously injured at first. All the scales were destroyed and later in the year the tree did as well as other trees and finally came out of the experiment uninjured.

Peach trees were treated in the same way without suffering any injury. A kerosene resin wash made in the following proportions was tried: 1 oz. of resin for every 75 cc. of kerosene. The solubility of resin in kerosene, expressed in ordinary terms, is 1 oz. in 2½ ozs. kerosene; or, about 3 lbs. in 1 gal. When used in this full strength peaches and some plums showed considerable injury. In general, the results did not encourage the use of this mixture.

An orchard of mixed fruits was treated for San José scale with undiluted kerosene. The first application was made September 30 by means of a Vermorel nozzle. The Bartletts were sprayed again in December; altogether 2,244 trees were sprayed with 185 gal. of kerosene. The four-year old trees received each about 1 pt. of kerosene. The Bartletts endured 2 applications without injury and the applications before January 1 produced absolutely no bad result.

The author has experimented with a mixture of kerosene and water, and comes to the following conclusion regarding its use: The mechanical mixture of kerosene and water, as applied by means of the Deming sprayer, has proved itself exceedingly useful against the San José scale. At the rate of 1 part kerosene to 5 parts water, it killed the young scales and did not in the least harm any tree to which it was applied. Even peaches could be drenched with it repeatedly without marked injury. In the use of whale-oil soap, the author found 1 lb. to 1 gal. of water produced a slight scorching but no real injury, and that the effectiveness of a mixture of 2 lbs. whale-oil soap and 1 gal. of water was no greater than a mixture of half that strength. The addition of lime to whale-oil soap was found to render it entirely ineffective.

The work of the year upon the San José scale showed that in some cases a mechanical mixture of kerosene and water in the proportion of 1:5, when applied about the middle of June, destroyed all the scales upon a large proportion of the trees. In New Jersey there is said to be three full and a partial fourth brood of the scale. The larval swarm is most numerous in September and October, and the greatest danger from the spread of the insect occurs at that time. The author states that where trees are only moderately infested the kerosene and water mixture gives the best results when sprayed upon the trees about June 15, with another application a few days later. The fungus disease *Sphærostilbe coccophila* is reported as present in New Jersey to some extent and as a help in the destruction of the scale. The importation of the Japanese coccinellids (*Chilocorus similis* and *C. tristis*) was apparently unsuccessful.

Brief notes are given on the occurrence and life history of the periodical cicada in New Jersey.

The author relates the life history and appearance of the strawberry-leaf roller (*Phoxopteris comptana*), and recommends for the destruction of this insect a thorough spraying with arsenate of lead at the rate of 15 oz. in 80 gal. of water about the middle of May; or, as a substitute for arsenate of lead, Paris green may be used at the rate of 1 lb. in 150 gal. of water. If the bed is new and is to remain for another year, the plants could be mowed down immediately after berry picking and burned in order to destroy the insect in the larval or pupal stage.

An account is given of the history of the common asparagus beetle (*Crioceris asparagi*) and of the 12-spotted asparagus beetle (*C. 12-punctata*). Among the natural enemies of the common asparagus beetle are mentioned *Stiretrus anchora* and *Megilla maculata*. As remedies the author suggests the destruction of all volunteer asparagus in the field and permitting a certain number of young shoots in each bed to grow as traps for the eggs and their subsequent destruction. The larvæ may also be destroyed with fresh air-slaked lime. The same remedies are recommended for the 12-spotted asparagus beetle.

The tulip soft scale (*Lecanium tulipiferæ*) is reported as gradually increasing and as being an important enemy of the tulip tree. The insect is described and figured and the methods of its distribution from one tree to another are suggested. *Lætilia coccidivora* is reported as being an effective destroyer of this scale. The author states that the insecticide applications should be made preferably in September. Spraying with a mechanical mixture of kerosene and water is said to be very effective against this insect as well as undiluted kerosene, but the latter remedy is more apt to injure the tree.

Entomological notes, W. E. BRITTON (*Connecticut State Sta. Rpt 1898, pp. 269–275*).—Brief notes are given on injuries caused by the squash ladybird. *Macrobasis unicolor* is reported as injuring *Genista tinctoria*. *Serica trociformis* is said to have eaten the foliage of the hornbeam. The elm-leaf beetle is reported as injurious during the year. *Xyleborus dispar* was found in the trunks of plum trees. The oak pruner is reported as having caused considerable damage to oak trees. Experiments were conducted in spraying fruit trees with pure kerosene oil for the San José scale. The insects were killed and little damage was done to the trees where the application was not heavy. One Japan plum tree, which was badly incrusted with scale, was thoroughly drenched with kerosene with the result that the branches of the tree were badly killed back. Brief notes are given on the habits of the following insects: Elm scale, oyster shell bark louse, scurvy bark louse, rose scale, tulip scale, *Schizoneura pinicola*, pear psylla, zebra caterpillar, *Gortyna nitela*, and Angoumois grain moth.

Trials against larvæ of the May beetle, 1898, O. HÖFFDING (*Tidsskr. Landökon., 1899, No. 8–9, pp. 369–401*).—The trials were conducted for the purpose of ascertaining whether attacks of May beetles (*Melolontha vulgaris*) can be minimized or prevented by the application of special fertilizers. Four different farms cooperated in the trials. Superphosphates, nitrate of soda, and kainit were applied singly and all three together. The results showed that none of the materials was able to kill the larvæ of the beetle during the wet season of 1898, nor cause them to remain deeper in the ground and thus below the roots of cultivated plants. One-sided fertilization or very heavy application of the complete fertilizers did not reduce the depredation of crops by larvæ in the seasons of 1897 and 1898 to such an extent as to make the use of fertilizers for that purpose profitable.—F. W. WOLL.

The bont tick (Amblyomma hebræum), C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 15* (*1899*), *No. 11, pp. 728–743, fig. 1*).—In this article the author presents an account of the appearance, habits, life history, and distribution of the bont tick. This tick has been found upon all kinds of stock, as well as upon ostriches and man. The female, when fully distended with blood, drops to the ground, and after a short period begins the deposition of the eggs. The number of eggs which are laid by a single female varies from 11,000 to 17,000, and from 3 to 9 weeks are required for their deposition. The larval ticks are 6-legged and gather upon grass tops, from which places they make their way to passing animals. These larvæ, after fully distending themselves with blood, drop to the ground, when molting occurs, and the tick passes into the nymph stage. The nymphs in turn find their way to the skin of domestic animals, where they become gorged with blood and then drop off. After another molting the tick passes into the adult stage. It was shown that these ticks may live for 3 months without food.

American vines and the phylloxera situation in the Canton de Vaud (*Les vignes américaines et la situation phylloxérique dans le Canton de Vaud. Sup. Chron. Agr. Cant. Vaud, 1899, pp. 110, figs. 7*).—This paper is a report of the viticultural station of Lausanne. A general account is given of the introduction of the phylloxera upon American vines and of the subsequent struggle of the vineyardists with this insect. At the present time large areas of vineyards in France, Spain, Hungary, Italy, and Switzerland have been reset with grafted stock, the stock being of American origin. An account is given of the practices adopted for the propagation and culture of American stock, of the process of grafting, and of the growth, development, and vigor of grafted vines. In the Canton de Vaud the adoption of American stock has not been as general as in many other localities. It is recognized that the process adopted is an inconvenient and laborious one, and some vine growers have preferred the extermination of their vineyards and resetting with native stock rather than adopt American stock and thereby allow the phylloxera to remain in the soil. The complete annihilation of the phylloxera, however, is such a difficult matter and requires so long a delay to insure its successful accomplishment that the adoption of American stock is urgently recommended for certain localities in this Canton.

Insects detrimental and destructive to timber and timber products, A. D. HOPKINS (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 103–108*).—The author classifies the chief insects which are destructive to timber under 2 groups, bark miners and wood miners.

Notes are given on the habits and economic importance of the following scolytid bark miners: *Dendroctonus frontalis, D. simplex, Scolytus* *quadrispinosus*, *Pityophthorus minutissimus*, and *Polygraphus rufipennis*. Under the head of buprestid or flat-headed bark borers the author treats briefly of *Melanophila fulvaguttata* and *Agrilus bilineatus*. Brief notes are given on the following wood miners: *Lymexylon sericeum*, *Eupsalis minuta*, and *Corthylus columbianus*.

Among the insect enemies of timber the author considers the 2 following species: *Lyctus striatus* and *Phymatodes variabilis*.

In order to control the destructive activity of timber insects the author concludes from a long experience that—

> "By slight changes in the method of cutting, manufacturing, and marketing timber and timber products, the conditions will be rendered unfavorable for the attack of insects, and that, owing to the fact that most timber-infesting insects prefer to attack sickly or recently felled trees, their depredations on the more valuable living timber can often be prevented by simply girdling or cutting a few inferior trees at the proper time each year. These so-called trap trees will attract the insects, and after their eggs are deposited and hatched, the young may be destroyed by removing the bark or burning the trees."

Quarantine against foreign insects—how far can it be effected? J. B. SMITH (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 90–100*).—The paper is in the nature of a discussion of the proposed national inspection law for nursery stock. The author calls attention to the great difficulty which inspectors must experience in detecting various insects when present upon nursery stock. The fact that insects may be found upon all parts of plants which may not be connected with any agricultural industry, under the bark, in the packing, and in wood, renders it practically impossible for any inspector to give a certificate which is entirely reliable.

The author believes, nevertheless, that such a law will have the good effect of making nurserymen and shippers more careful than they otherwise would be, and thus perhaps prevent the importation of some injurious insects.

The most injurious insects which have been imported from foreign countries have got into the country in quite unexpected ways and under circumstances that would have rendered their detection impossible by inspection.

History and present condition of sericulture in the world, D. ROSSINSKI (*Selsk. Khoz. i Lyesov., 195 (1899), Nov., pp. 257–283*).—This article includes the following items: Historical outline of silk culture; origin of the mulberry silkworm; beginning of its domestication; silk culture of Asia, western Europe, southern Russia, and northern Russia; geographical and statistical outline of sericulture in China, Italy, France, western Europe, Africa, America, Caucasus, and Turkestan; and the industries which are related to silk culture.

Bibliography of clinical entomology, J. C. HUBER (*Bibliographie der klinischen Entomologie. Jena, 1900, pt. 4, pp. 27*).—This part contains a list of literature upon *Sarcoptes scabiei* from 1786–1900, with additional lists of literature on related diseases of animals, and an appendix on *Symbiotes felis*.

Insect migration between Germany and the United States, L. KRÜGER (*Insekten-Wanderungen zwischen Deutschland und den Vereinigten Staaten. Stettin, 1899, pp. VIII+174*).—This work constitutes an elaborate digest of the literature on the migration of insects between the two countries named. In the author's opinion no American insect of economic importance has established itself in Germany and no such occurrence is likely to take place. The author believes that the differences in climate of the two countries will tend to prevent it.

Extensive bibliographical and economic notes are given on more than 80 species of injurious insects, with special reference to their original home and subsequent distribution.

Migration and dispersal of insects. Lepidoptera, J. W. TUTT (*Ent. Rec. and Jour. Variation, 11 (1899), No. 12, pp. 319–324*).—Observations upon a number of species of butterflies and moths.

The histogenesis of the imaginal muscles of the Hymenoptera, J. ANGLAS (*Compt. Rend. Soc. Biol. Paris, 11. ser., 1 (1899), No. 36, pp. 947–949*).—An anatomical study of the metamorphosis of bees and wasps.

Annual report for 1899 of the zoologist, C. WARBURTON (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 4, pp. 667–678, figs. 5*).—This report contains notes on the habits, life history, and remedies for *Gastrophilus hæmorrhoidalis, Coccinella 7-punctata, Diplosis pyrivora, Carpocapsa pomonella, Hoplocampa testudinea, Coleophora nigricella, Chermes laricis,* and *Zeuzera æsculi.*

Report of the State Entomological Station of Sweden for 1898, S. LAMPA (*Meddel. K. Landtbr. Styr., 1899, No. 53, pp. 70*).

Report of the State Entomologist for 1898, W. M. SCHÖYEN (*Aarsber. Offent. Foranst. Landbr. Fremme, 1898, pp. 75–106*).

General index to Miss Ormerod's reports on injurious insects, 1877-1899, R. NEWSTEAD (*London, 1899, pp. 58*).—Contains a general index, a plant index, and an animal index.

Report on the injurious insects of Finland for the year 1898, E. REUTER (*Landtbr. Styr. Meddel.* [*Helsingfors*], *1899, No. 26, pp. 68*).—This report contains economic and biological notes on a number of injurious insects, among which may be mentioned *Charæas graminis, Tortrix paleana, Agriotes obscurus, Hadena secalis, Agrotis segetum, Meligethes æneus, Plutella cruciferarum, Athalia spinarum, Carpocapsa pomonella, Argyresthia conjugella,* and *Nematus ribesii.*

The author made a number of experiments with insecticides upon *Charæas graminis,* during which he employed the following substances: Antinonnin, one part in 500 parts of water, lysol in various strengths, and Paris green.

In combating the codling moth the author used Paris green sprays in various proportions, and concludes from his work that trees should be thoroughly covered with the spray, but not to such an extent that the liquid will drip from the trees.

Detailed notes are given of the distribution and life habits of *Argyresthia conjugella.*

Insects injurious to cereals, V. MAYET (*Prog. Agr. et Vit., 16 (1899), No. 51, pp. 715–719*).—Notes on *Siphonophora avenæ, S. cerealis, S. granaria* (which are considered distinct species by the author), *Forda vacca,* and *Pemphigus boyeri.* The first three named species are parasitized by *Aphidius avenæ.* On small plats of cereals the author used a 2 to 3 per cent solution of tobacco and soap in water. *F. vacca* and *P. boyeri* attack the roots of cereals. Remedies which are effective against phylloxera may also be used against these insects.

Injurious insects of the garden and greenhouse, and means of destroying them, D. KARAMZIN (*St. Petersburg, 1899, pp. 84, ill.*).—The author's articles published in "Derevnya" for the current year are brought together in book form.

Tabulated list of orchard insect pests affected by spraying, F. V. THEOBALD (*London, 1899, pp. 19*).—A list of injurious insects with the date of appearance of eggs and larvæ, formulas for preparing insecticides, and directions for their application.

Insects attacking the Spanish or sweet chestnut, F. V. THEOBALD (*Jour. Southeast. Agr. Col., Wye, 1899, No. 8, pp. 46–54, figs. 4*).—This article contains an account of the habits, life history, and remedies for the following insects: *Porthecia* *auriflua, Fumea nitidella, Tortrix viridana, T. dumetana, T. ribeana, Lozotænia rosana, Carpocapsa splendana, Coleophora lutipennella Attelabus curculionides*, and *Smynthurus fusca*.

The clay-colored weevil, F. V. Theobald (*Jour. Southeast. Agr. Col., Wye, 1899, No. 8, pp. 40–46, figs. 3*).—Notes on *Otiorrhynchus picipes*. This insect causes injury to peas, beans, turnips, kale, vines, raspberries, apples, plums, elms, etc. It feeds upon the leaves and also the wood. The larvæ hatch from eggs which are deposited in the ground and live through the winter. The adults appear in May and June. Among the natural enemies of this insect the author mentions *Cerceris arenaria* and *C. labiata*.

It is recommended that the weevils be jarred from the plants which they infest and be caught by means of tarred boards or other receptacles. Against the larvæ the following spray was found effective: Carbolic acid and water in the proportion of 1 pint of crude carbolic acid to 10 gal. of water.

The codling moth and means of combating it, Y. Treiner (*St. Petersburg: Dept. Agr., 1899, pp. 16, figs. 5*).—A discussion of the habits and life history of the moth and of the use of insecticidal sprays against it.

The pear and cherry sawfly, Eriocampa limacina (*Jour. Bd. Agr.* [*London*], *6* (*1899*), *No. 3, pp. 341–345, fig. 1*).—A brief account of the appearance and life history of this species. In combating the insect it is recommended that the ground under infested trees be thoroughly cultivated and that quicklime be scattered upon the ground and cultivated in. Paraffine emulsion is also said to be effective. The emulsion is made by dissolving a half pound of soft soap in a gallon of boiling water, then adding 2 gal. of paraffine oil, and subsequently churning the mixture together.

Some recent developments in the San José scale problem in Ohio, F. M. Webster (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 112–119*).—This paper is an abbreviated and somewhat altered form of Ohio Station Bulletin 103 abstracted in E. S. R., 11, p. 267.

The Hessian fly, M. Bartlet (*Rpt. Farmers' Inst. Manitoba, 1899, pp. 41–43*).—A brief account of the habits and life history of this insect.

Some problems connected with the attacks of Jassidæ upon grasses, H. Osborn (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 101, 102*).—This is an abstract of an article read by the author in which he calls attention to the problems in connection with this family of insects, which are awaiting a solution.

Among the problems which the author considers important are the geographical distribution of the different species, range of food plants for each species, determination of the number of annual generations, and the time of occurrence of each stage.

Communication on a second generation of Vanessa io, M. Ude (*Ent. Nachr., 25* (*1899*), *No. 23, p. 366*).

Rocky Mountain locusts, H. McKellar (*Rpt. Farmers' Inst. Manitoba, 1899, pp. 38–41*).– Notes on *Melanoplus spretus* and *M. atlanis*.

Notes on the New Zealand Acrididæ, F. W. Hutton (*Trans. and Proc. New Zealand Inst., 31* (*1898*), *pp. 44–50, pl. 1*).

Revision of the New Zealand Phasmidæ, F. W. Hutton (*Trans. and Proc. New Zealand Inst., 31* (*1898*), *pp. 50–59*).

The Bugong moth (Agrotis infusa), W. W. Froggatt (*Agr. Gaz. New South Wales, 10* (*1899*), *No. 12, pp. 1252–1256, map 1*).—A description of the food plants and life history of this insect. Among the remedies recommended, mention may be made of the ditch and pit method, the use of a heavy roller and Paris green spray on trap crops. A fungus disease was discovered which assisted materially in the control of this insect and has been determined by M'Alpin to be a new species which has been named *Entomophthora australis*.

Three galls found on the yew, F. V. Theobald (*Jour. Southeast. Agr. Col., Wye, 1899, No. 8, pp. 54–58, figs. 4*).—Brief notes on *Phytoptus taxi, Chermes taxi,* and *Cecidomyia taxi*.

An attack of Crepidodera rufipes on tares, F. V. THEOBALD (*Jour. Southeast. Agr. Col., Wye, 1899, No. 8, pp. 38–40*).—Brief notes on the life history of this insect and a few related species.

The Oxyopisthinæ, H. J. KOLBE (*Stettin. Ent. Ztg., 60 (1899), No. 1–6, pp. 3–138*).—The author establishes a new group of snout beetles of the subfamily Calandridæ. New species are described.

The digestive organs of Periplaneta orientalis and Blatta germanica, A. PETRUNKEWITSCH (*Zool. Jahrb., Abt. Anat., 13 (1899), No. 1, pp. 171–190, pl. 1, fig. 1*).—An anatomical and physiological study of these insects, with an extensive bibliography.

Life habits of Porthetria dispar, H. GAUCKLER (*Illus. Ztschr. Ent., 4 (1899), No. 23, p. 361*).

Notes on the Pyralidæ, P. C. T. SNELLEN (*Tijdschr. Ent., 42 (1899), No. 1–2, pp. 58–95, pls. 2*).—Descriptive and biological notes on a number of species of this family.

Habits of the imago of Smerinthus ocellatus, L. J. LAMBILLION (*Ent. Rec. and Jour. Variation, 11 (1899), No. 12, pp. 330, 331*).—Notes on the egg-laying habits of this insect.

Tinea granella, V. MAYET (*Prog. Agr. et Vit., 16 (1899), No. 52, pp. 735–737*).—A description of this insect, with an account of its habits and life history. Species of Hemiteles and Campoplex, as well as the mite *Sphærogyna ventricosa* are mentioned as natural enemies of this insect.

On the habits of Dermestes vulpinus, A. T. POTTER (*Trans. and Proc. New Zealand Inst., 31 (1898), pp. 104–105*).—This insect is reported as injurious to bones and wood. The eggs hatched within 4 to 5 days and the pupal stage lasted 13 days.

Pediculoides ventricosus, BRUCKER (*Compt. Rend. Soc. Biol. Paris, 11. ser., 1 (1899), No. 37, pp. 953–955*).—Mites of this genus have been found parasitic upon the larvæ of insects and on man. The forms found under these different conditions have been considered different species. The author examined specimens which came from the larvæ of Callidium and from man and came to the conclusion that they belonged to one species, and that its normal host is an insect larva.

Collops bipunctatus as an enemy of the Colorado potato beetle, C. E. MEAD (*Amer. Nat., 33 (1899), No. 396, pp. 927–929*).—This insect is reported as feeding upon the eggs and larvæ of the Colorado potato beetle of New Mexico.

Mustard dross and its effect on wireworm, F. V. THEOBALD (*Jour. Southeast. Agr. Col., Wye, 1899, No. 8, pp. 31–35*).—In this article the author describes some experiments which were conducted for the purpose of determining the value of mustard dross in preventing the ravages of the wireworm. The results obtained indicate that this substance is worthless for preventing the attacks of wireworms, and is distinctly harmful, since it appears to be favorable to the multiplication of wireworms and destroys or drives away the earthworms.

A new method of disinfection by means of formaldehyde, C. ENOCH (*Hyg. Rundschau, 9 (1899), No. 25, pp. 1274–1283*).

FOODS—ANIMAL PRODUCTION.

Studies on bread and bread making, H. SNYDER and L. A. VOORHEES (*U. S. Dept. Agr., Office of Experiment Stations Bul. 67, pp. 52, figs. 3, pls. 2*).—This includes two separate papers.

Studies on bread and bread making at the University of Minnesota in 1897 and 1898, H. Snyder (pp. 7–36).—The author's experiments have to do with the composition of a number of samples of Minnesota bread and flour as compared with their cost; the loss of dry matter, carbon, and nitrogen in bread making; the production of soluble carbohydrates and acids; the behavior of proteids; and the changes in the solubility of fat during bread making. Two experiments on the digestibility of bread made from patent roller process flour and bakers' grade flours are also reported.

"The results of these investigations may be summarized as follows:

"(1) In ordinary bread making about 1 per cent of carbon dioxid was given off during the rising and baking processes and a little more than 1 per cent of alcohol was formed. There was also given off during baking a small amount of volatile acid products.

"(2) The determination of the volatile products given off during bread making showed a total loss of 0.74 per cent of the total carbon in the flour, which is equivalent to about 1.68 per cent of starch.

"(3) When special care was taken in bread making, the analyses of the flour and the bread showed an average loss of 1.58 per cent of the total dry matter of the flour.

"(4) The analyses of the gases produced, and of the flour and bread, indicate that for good bread making the total losses need not exceed 2 per cent of the flour used, and that it is possible to reduce the losses to 1.1 per cent.

"(5) The amount of alcohol recovered in bread making was found to be less than the theoretical amount corresponding to the carbon dioxid produced. This discrepancy is not due to alcohol remaining in the loaf, since no appreciable amounts of alcohol were recovered from fresh bread. When alcohol was used in making bread, the action of the yeast was apparently normal.

"(6) In bread making the starch undergoes both physical and chemical changes. From 3 to 4 per cent of soluble carbohydrates were found in the bread, indicating that less than 8 per cent of the total starch was changed from insoluble to soluble forms. The physical changes which many of the starch granules undergo are marked. Some are partially disintegrated, while others are ruptured.

"(7) Normal flour contains a small amount of acid. During bread making variable amounts of acid were produced by the action of the yeast. A part of the acid formed appears to unite with the proteids. In acid doughs the acid renders the proteids more soluble and changes the composition of the gluten.

"(8) When bread was made from dough of low acidity there was less water-soluble nitrogen in the bread than in the flour, because of the coagulation of the albumin and globulin during baking. In bread made from doughs of high acidity the amount of water-soluble nitrogen was increased. This is due to the action of the acid on the insoluble proteids. The gliadin is rendered soluble, which changes the gliadin-glutenin ratio of the bread.

"(9) The power of expansion which the gluten of a flour possesses determines very largely the physical properties of the bread. Some glutens possess an expansive power four or five times greater than others.

"In general it may be said that in good bread making the loss of dry matter and of nitrogen need not exceed 1.6 per cent of the total amounts in the flour. In poor bread making the losses may exceed 6 per cent. In good bread making the losses are equivalent to about 3 lbs. per barrel of flour, while with poor bread making the losses may exceed 12 lbs. per barrel."

Losses in the process of making bread, *L. A. Voorhees* (pp. 37–51).—A number of experiments were made to study the loss of material which has been observed in making and baking bread.

"[From the results obtained] it seems proper to conclude that at high temperatures there is a partial volatilization of the vegetable fat in bread making, especially in the presence of escaping water vapor, and, in addition, an oxidation of the residual organic matter. When animal fat was added to the dough there seemed to be an occlusion of fat, probably due to the formation of dextrin. . . .

"From the investigations reported in this bulletin it is evident that some of the apparent loss of ether extract in bread making was due to heat employed in baking the bread and to the heat employed in drying the samples for analysis.

"When samples of flour, dough, and bread were dried in air or in hydrogen previous to analysis, an apparent loss of ether extract was observed. It should be remembered, however, that since ether extract is usually determined in a sample used for determination of dry matter, the materials have been subjected to two dryings, one previous to analysis and one during analysis. When samples of flour and dough dried over sulphuric acid were analyzed there was also an apparent loss of fat. The loss was, however, smaller than was the case when samples dried in air or hydrogen were analyzed. In this case the samples had been submitted to the action of heat but once; that is, in the determination of dry matter in the sample before extracting with ether. Samples of dough dried over sulphuric acid were extracted with ether without any further drying; that is, without submitting them to the action of heat. In this case slightly more ether extract was recovered than when similar samples were extracted after drying in an oven for the determination of dry matter. In all these cases, however, there was an apparent loss of ether extract; that is, when flour is made into dough and dried or baked, all the ether extract of the flour can not be recovered. . . .

"These considerations indicate that the usual custom of drying fodder and food samples in air or in hydrogen in a drying oven previous to extraction with ether should be carefully investigated in view of the possible errors in the estimation of ether extract involved."

Food products, A. L. WINTON ET AL. (*Connecticut State Sta. Rpt. 1898, pp. 103-223, pls. 2*).—The Connecticut pure food law is quoted, and detailed statements are made concerning foods and condiments examined in accordance with the law. The following table shows the total number of samples of different materials examined, as well as the number of samples in each case found to be pure, adulterated, and treated with preservatives (borax or salicylic acid) but otherwise not adulterated:

Number of samples of food products found to be pure, adulterated, and containing preservatives.

Food products.	Unadulterated.	Adulterated.	Contained preservatives.	Total.
Collected by the station—				
Purchased in Connecticut market:				
Jellies	27	43		70
Preserves, jams, marmalades, etc	6	45		51
Teas	89			89
Coffee	34	11		45
Coffee compounds	22			22
Coffee substitutes	6			6
Flour	25			25
Ginger	67	24		91
Malt liquors	35		12	47
Sausage	5		14	19
Honey	27	10		37
Maple sirup	3			3
Milk	13			13
Cream	19		4	23
Canned soups	32			32
Canned vegetables	65			65
Chili sauce		1		1
Mince meat	9			9
Ground spices in labeled packages	142	28		170
	626	162	30	818
Purchased from importers:				
Pure spices, spice by-products, etc	125			125
Total collected by the station	751	162	30	943

Number of samples of food products found to be pure, etc.—Continued.

Experiments on the metabolism of matter and energy in the human body, W. O. ATWATER and F. G. BENEDICT (*U. S. Dept. Agr., Office of Experiment Stations Bul. 69, p. 112*).—A technical bulletin prepared with the cooperation of A. W. Smith and A. P. Bryant recording the details of 6 experiments with man made with the respiration calorimeter previously described (E. S. R., 9, p. 863; 11, p. 372). Check experiments are also reported in which heat was generated in the respiration chamber by means of an electric current and by the combustion of alcohol. An incidental feature of 2 of the experiments reported was the partial study of the food value of alcohol when used in limited quantities in the daily diet.

Feeding and respiration experiments on the nutritive value of cellulose and certain feeding stuffs rich in cellulose, O. KELLNER (*Chem. Ztg., 23 (1899), No. 79, pp. 828, 829*).—An abstract of a paper describing some of the recent work of the Möckern Experiment Station, presented at the meeting of the Association of German Naturalists and Physicians in Munich in 1899. No experimental data are given in the abstract, which was in effect as follows:

Recently a large number of experiments with ruminants have been made at Möckern on the metabolism of matter and energy. Forty-four were metabolism experiments, each of 14 days' duration, and 184 were respiration experiments each of 24 hours' duration. The author spoke only of those experiments which had to do with the value of cellulose and materials rich in cellulose for producing gains. In measuring this value starch served as a unit of comparison. Thirteen experiments have been made at Möckern with starch. The general method was as follows: In each experiment the ration was so arranged that the subject (a full grown steer) gained a little fat and muscular tissue. The metabolism of matter and energy was estimated in this period and also in a following period in which the basal ration was increased by the addition of single nutrients or some feeding stuff. Deducting the values of the first period from those obtained in the succeeding period gave the figures from which the "productive value," i. e., the value of the nutrient or feeding stuff for producing gains, could be calculated. Suitable corrections were necessary for slight variations in the basal ration and the weight of the animals from day to day. This latter factor needs some explanation. If an animal gains in weight on account of an abundant food supply, the minimum amount of material and energy required for maintenance increases also. This increase is not proportional to the body weight, but to the surface area, which, however, is a function of the body weight. If A and B represent different weights of an animal, the corresponding surface areas would be as $\sqrt[3]{A^2} : \sqrt[3]{B^2}$. Corresponding to this ratio the minimum requirements for increased weight increases more slowly than the surface area.

If the minimum requirement per 1,000 kg. live weight of digestible nutrient in the form of medium meadow hay (6.58 kg.) for a steer weighing 500 kg. is taken as 100, the amount required by a steer weighing 600 kg., 700 kg., and 800 kg. are, respectively, equal to 94.1, 89.5, and 85.6 kg. Since the minimum requirement has been determined at Möckern for 7 individuals up to the present time, this value may be calculated for a steer of any given weight by the above proportion. If the minimum requirement increases while the ratio remains constant, the gain in weight decreases proportionately, and *vice versa.* This point must also be taken into account in comparing the effect of a basal ration plus added material.

The productive value of the following feeding stuffs was determined: (1) Starch (from potato); (2) extracted rye straw (prepared by treating straw with alkali under 7 atmospheres' pressure); (3) medium meadow hay, and (4) well-ripened wheat straw. The extracted rye straw contained 78.7 per cent crude fiber, 20.46 per cent nitrogen-free extract, 0.64 per cent protein, and 0.2 per cent ether extract. The greater part of the incrusting substance was removed. The residue contained, however, 32.9 per cent pentosan. In the experiments with steers the basal ration contained per head per day 2 to 2.5 kg. of starch, 3 kg. of extracted rye straw, 3.5 to 4 kg. of medium quality meadow hay, 4 kg. of oat straw, and 4 kg. of wheat straw. These feeding stuffs did not give up to the body their entire potential energy since there are losses due to the formation of methan and urine. It was found that the isodynamic equivalent of 100 parts of digestible starch was furnished by 103 parts of extracted straw, 108 parts of meadow hay, 100 parts of oat straw, or 113 parts of wheat straw. These are the substituting values for the different materials when they form part of a basal ration. The ratio is different when they form part of a ration for production. When the gain in muscular tissue was reduced to the isodynamic amount of fat and added to the fat gained, it was found that the starch added to the basal ration caused a gain of 217 gms. per kilogram of digestible matter, and extracted straw, 247 gms. That is, the extracted straw, which is very rich in cellulose, was not inferior to starch for producing gain. It must be remembered, in reference to the above statement, that 85.4 per cent of the digestible portion of extracted straw consists of crude fiber. If the latter had been found to possess only a slightly inferior value to starch, the results would have been entirely different. The feeding stuffs rich in crude fiber (meadow hay and unextracted straw) gave very different results, as was to be expected. They induced considerably smaller gains than the extracted straw or than starch. The solid layer of the cells, the material incrusting the cell tissues, the liquified substance of the cells, and the imperfect division of the coarse fodder are very probably the cause of the inferiority of the digestible nutrients contained in such feeding stuffs. In view of the hardness, etc., the coarse fodder must undergo more cleavage due to the agency of micro-organisms and requires a larger amount of energy for the labor of chewing and digesting, which must be deducted from its productive value, than the easily digested starch or the extracted straw, which consists of individual fibers from which the greater part of the incrusting substance is removed. The harder and more compact the feeding stuff, the lower its productive value. Of the coarse fodders experimented with, wheat straw had the least productive value, meadow hay the highest, while oat straw was almost equal to meadow hay. According to the above considerations, it would require, in that portion of a ration used for the production of gain, 374 parts of wheat straw, 57 of oat straw, 153 of meadow hay, or 96 of extracted straw to equal 100 parts of starch, these quantities representing digestible matter in each case. In other words, the values of these feeding stuffs for production are entirely different from their values for maintenance. These experiments emphasize very plainly the rôle of coarse fodder. In rations for maintenance, the value of coarse fodders is determined or limited solely by their content of digestible organic substance. But in a ration for production they should be used only so far as they supply the minimum requirements of the animal. The nutrients which really are utilized for production should not be supplied by coarse fodders, but by those feeding stuffs which are most easily digested. The experiments also show that decreasing the labor of chewing and digesting hard feeding stuffs by suitable methods of preparation is profitable. Such methods of preparation not only increase the palatability, but also increase the productive value of the material.

Contribution to the study of the metabolism of ruminants, O. HAGEMANN and G. ABATI (*Arch. Anat. u. Physiol, Physiol. Abt., 1899, Supt. pt. 1, pp. 111–140*).—The authors' investigations were made with a sheep. Food, urine, and feces were analyzed and their fuel value determined. In addition a large number of experiments were made in which the respiratory quotient was determined. The sheep had a tube inserted in the trachea to facilitate these experiments. The food consisted of maize meal and alfalfa hay. Many determinations were made of the respiratory quotient during chewing, digesting, sleeping, and resting, and the proportion of the day occupied by the different processes was calculated. The principal conclusions follow:

The metabolism of a sheep may be very accurately studied with the aid of calorimetric examinations of the food, urine, and feces, the determination of the carbon in these materials, and the determination of the ratio of oxygen consumed to carbon dioxid excreted. When 350 gms. of maize meal and 600 gms. of alfalfa hay were fed daily, the metabolism of energy of sheep was increased 5.5 per cent over that observed during hunger.

In order to study quantitatively and qualitatively the processes of fermentation which take place in the digestive tract of sheep, a respiration apparatus which permits the measurement and analysis of the total carbon dioxid and other gases produced is essential.

The early feeding of mangels to stock, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 3, pp. 559–566*).—Experiments on the early feeding of mangels to steers and sheep are reported. The principal deductions follow:

"Well-ripened mangels given in moderate quantity, say, 28 to 30 lbs. per head daily, can be quite well fed to fattening bullocks in the early stages, in place of swedes, if along with them be given either common cotton cake, bean meal, or a plentiful supply of long hay. As soon as the quantity of mangels reaches 35 to 40 lbs. per head daily, scouring will probably appear. When this is the case the giving of long hay in quantity will prove to be palliative. Both undecorticated cotton cake and bean meal will soon check the tendency to scour, and . . . bean meal proves the more satisfactory by giving the larger increase in live weight. . . .

"[In the test with sheep] there was, however, no scouring effect whatever produced by the feeding of the mangels, and it would appear, therefore, that mangels can quite well be fed to sheep from the commencement of root feeding, in place of swedes, if about ½ lb. per head daily of undecorticated cotton cake be given along with the food.

"Attention has been directed to the harm that may be caused to male sheep by the feeding of mangels freely, there being a tendency to act on the kidneys, produce increased secretion of urine, and, in extreme cases, the formation of crystals in the urethra. In the above experiment half the sheep were males and half females. The sheep that died on April 6 was a male, and the kidneys were certainly affected, though the bladder was not."

Gorse as a food for sheep, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 3, pp. 567–573*).—The possibility of raising gorse on a poor sandy piece of hillside at the Woburn Experimental Farm, where other crops would not grow successfully, led to experiments with sheep to determine the feeding value of gorse.

"In commencing this experiment it was intended to let gorse replace, as far as it would, the use of roots, seeing that in the event of a failure of roots, or a short root crop, gorse might come in as a very useful substitute, especially in the case of very poor land. A main point of the experiment was, therefore, to see to what extent the replacement of roots by gorse could be effected. The results show very clearly that the replacement could only be made to a limited extent and that at most 2½ lbs. of gorse per head daily would be consumed, taking the place of, say, 6 lbs. of roots. But with this limitation the gorse did exceedingly well as a food and exercised a pronounced benefit upon the sheep, alike as regards their general health, their increase in live weight, and the excellence of the meat produced, so that the use of gorse as an additional food to sheep is decidedly to be recommended."

Whole corn compared with corn meal for fattening hogs, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 59, pp. 39–46*).—This bulletin contains an account of the pig-feeding experiments at the station in 1897 and 1898.

Whole corn compared with corn meal as a food for fattening hogs (pp. 39–44).—A test to compare whole corn with corn meal was made with 9 pigs divided into lots of 3 each. Lots 1 and 2 were Poland China and Duroc Jersey crosses, and lot 3 Poland China and Berkshire crosses. All the pigs were about 6½ months old at the beginning of the test, which covered 2 periods of 2 weeks each. Lot 1 was fed whole corn and lots 2 and 3 corn meal. Lot 1 consumed during the test 819.3 lbs. of whole corn; lots 2 and 3, 951 and 748.4 lbs. of corn meal, respectively. Lot 1 gained 141.4 lbs., consuming 5.79 lbs. of whole corn per pound of gain; lots 2 and 3 gained 199.9 and 161.4 lbs., consuming, respectively, 4.75 and 4.63 lbs. of corn meal per pound of gain. The authors discuss the tests and summarize the results obtained by other stations on this subject. "The average of these different experiments and our own results indicate that unless a farmer is located very close to a mill or has one upon his own farm, at present prices it will not pay to grind corn for hogs."

Soaking corn for hogs (pp. 44–46).—The comparative value of whole corn soaked in water until soft and corn meal mixed with water was tested with 2 lots of 6 pigs each, of the same crosses as in the preceding test. There were 4 sows and 2 barrows in each lot. The test began October 10, 1898, and closed December 5, being divided into 2 equal periods. Lot 1 was fed soaked whole corn and lot 2 corn meal, each lot being given all they would eat up clean. The 2 lots weighed at the beginning of the test 569.5 and 570.5 lbs., respectively, while the gains made were 555 and 581 lbs. Lot 1 consumed 2,138 lbs. of whole corn, or 3.85 lbs. per pound of gain; lot 2 consumed 2,384 lbs. of corn meal, or 4.1 lbs. per pound of gain. "As very few experiments have ever been performed to determine the effect of soaking grain upon its digestibility, the subject requires further study. The result of our experiment indicates, however, that it is good practice."

Poultry experiments, J. H. STEWART and H. ATWOOD (*West Virginia Sta. Bul. 60, pp. 49–66*).—Tests on the effect of nitrogenous and carbonaceous rations for laying hens, floored vs. unfloored poultry houses, and the effect of age of fowls upon egg production are reported.

A study of the effect of nitrogenous and carbonaceous rations when fed to laying hens (pp. 49–59).—Two tests on this subject are reported. In the first test, made in 1897–98, 6 lots were used with from 10 to 20 fowls in a lot, representing 3 breeds. Lots 1 to 3 were fed the nitrogenous ration, consisting of middlings, linseed meal, ground oats, and corn meal in varying proportions, together with ground fresh meat and bone, while lots 4 to 6 received the carbonaceous ration, of which corn meal was the principal constituent. In addition, all the lots had either boiled potatoes or steamed clover hay, and at night all the whole grain they would eat up clean, consisting of corn, oats, and wheat screenings, corn predominating for the lots fed the carbonaceous ration. The test covered 7 periods of 30 days each.

In discussing the financial side of the test, the feeding stuffs were rated as follows: Small potatoes 20 cts., corn 40 cts., and oats 32 cts. per bushel; hominy feed and corn meal each $14.50 per ton, brown middlings $15, ground oats $20, clover hay $5, and linseed meal $25 per ton; wheat screenings 50 cts. and fresh bone 25 cts. per hundred. During the first 2 months of the test, eggs were valued at 20 cts. per dozen and during the last 5 months at 12 cents. The results are calculated per 100 fowls, and are given in detail. The average results of the test follow:

Nitrogenous vs. carbonaceous rations for fowls, calculated per hundred hens.

	Ration.	Number of eggs laid.	Value of eggs.	Total cost of food.
Lot 1, White Leghorns	Nitrogenous	7,203	$81.39	$32.19
Lot 2, Light Brahmas	do	4,041	41.85	51.42
Lot 3, Rhode Island Reds	do	6,215	71.60	81.03
Lot 4, White Leghorns	Carbonaceous	3,392	40.38	28.48
Lot 5 Light Brahmas	do	2,274	26.28	45.19
Lot 6, Rhode Island Reds	do	4,042	52.40	26.52

According to the authors, the net profits per 100 hens from the lots fed the nitrogenous ration was $97.90, and from the lots fed the carbonaceous ration, $20.59.

The effect of the 2 kinds of rations on the fertility of eggs was tested in incubators. Sixty-six per cent of the eggs produced on the nitrogenous and 47 per cent of those produced on the carbonaceous ration were fertile. The average weight per hundred of the former eggs was 12.68 lbs., and of the latter, 11.57 lbs.

"At the beginning of the experiment, the 3 pens of fowls fed a nitrogenous ration weighed 1,344 lbs. (per 100 fowls), and at the end of the seventh period, 1,698 lbs. They consequently gained in weight 354 lbs., while the fowls fed a carbonaceous ration gained only 34 lbs. . . .

"Although the nitrogenous ration cost slightly more money, yet it was more profitable, because more eggs were laid and the fowls gained more in weight. The eggs from the fowls fed a nitrogenous ration were larger, more fertile, and hatched better and produced far more vigorous chicks than those laid by hens fed the carbonaceous ration. Both lots of fowls remained in a healthy, vigorous condition during the entire test."

The second test was made in 1898–99 with 4 lots of White Leghorn chickens, each containing 10 hens and 1 cock. Lots 1 and 3 were pullets; lots 2 and 4, old fowls. Lots 1 and 2 were fed the nitrogenous and lots 3 and 4 the carbonaceous ration. The test covered 7 periods of 30 days each. All the lots were fed a mash of ground feed in the morning, lots 1 and 2 receiving meat meal in addition during the first

4 periods and ground fresh meat and bone during the remainder of the test. During periods 2, 3, and 4, all the lots were given boiled sugar beets; but, "as the beets seemed to be making the fowls too fat, they were then dropped from the ration, although the fowls were very fond of them." All the lots were fed at night as much grain as they would eat up clean.

The results were calculated per 100 fowls. On this basis, lots 1 and 2 weighed 227 and 304 lbs. at the beginning and 272 and 273 lbs., respectively, at the close of the test; while lots 3 and 4 weighed, respectively, at the beginning 213 and 263 and at the close 250 and 300 lbs.

Calculated per 100 hens, the fowls fed the nitrogenous ration laid 7,555 eggs and those fed the carbonaceous ration 3,431. In the authors' opinion this test is in entire accord with that of the previous year.

Floored vs. unfloored houses for poultry (pp. 50-63).—Two trials are reported. The first included 6 lots of fowls, representing Black Langshan, Brown Leghorn, and Blue Andalusian breeds. Lots 1 to 3 were placed in pens in a portion of the poultry house which was floored with rough boards from 2 to 3 ft. above the ground and the other lots were kept in pens in the unfloored portion. The grain ration fed varied somewhat during the 5 months of the test, but was uniform for all lots.

> "The 3 flocks kept on the floor laid 10,859 eggs (calculated for 100 fowls), while those on the ground laid 13,948. This result was quite contrary to expectations, and can be explained only by the fact that the unfloored pens seemed to be somewhat warmer than the others, as the water in the drinking dishes in the floored pens would sometimes freeze, while in the unfloored pens it seldom did so.
>
> "Quite contrary to expectations, too, the health of the fowls in the unfloored pens remained almost perfect during the entire test. Only 2 fowls died of the roup, 1 from a floored and the other from an unfloored pen, and there was no other sickness of any kind."

A second test of the comparative value of floored and unfloored poultry houses was made in 1898-99 with 2 lots of Rhode Island Red fowls and 2 lots of Light Brahmas. One lot of each breed was kept in unfloored pens and 1 of each in floored pens.

Although the Brahmas did not lay during the test, they began to do so shortly after the test was finished. The health of the fowls seemed good, except in the case of lot 3, where 3 deaths occurred. It was uncertain whether these deaths were caused by the extremely cold weather which prevailed during a few days of the test or by other causes.

> "The result of 2 years' experiments with floored and unfloored houses shows that fowls remain in as healthy condition and lay as many or more eggs when kept in unfloored houses as they do when kept in houses provided with floors. . . . In building poultry houses it probably would be wise to raise the level of the dirt floor by first applying a course of 6 or 8 in. of cracked stone or gravel, and then covering this with a layer of dirt. Such a floor would always be perfectly dry, can be cheaply constructed, and probably would be satisfactory in every way."

The effect of the age of fowls upon egg production (p. 64).—The comparative egg production of pullets and old hens was tested with White and Brown Leghorns, the hens being 3 to 4 years old. The test with the White Leghorns began October 19, 1898, and covered 7 periods of 30 days each. The Brown Leghorns were fed for 4 periods of 30 days. The White Leghorns were the fowls used in the test reported above on the comparative value of nitrogenous and carbonaceous rations. The Brown Leghorns were given practically the same feed as the White Leghorns receiving the nitrogenous ration. The 3 lots of pullets, calculating results per 100 hens, laid during the test 6,209 eggs and the old hens 6,349. The 3 lots of pullets gained 143 lbs., while the old fowls gained 84 lbs.

Description of some Chinese vegetable food materials, W. C. BLASDALE (*U. S. Dept. Agr., Office of Experiment Stations Bul. 68, pp. 48, pls. 8*).—The author reports the composition and discusses the food value, etc., of a number of vegetable food materials in common use by the Chinese on the Pacific Coast of the United States. The bulletin contains many references to the literature of the subject.

Fish as food, C. F. LANGWORTHY (*British Food Jour., 1 (1899), Nos. 10, pp. 292–297; 11, pp. 324–327; 12, pp. 358–361*).—A reprint of Farmers' Bulletin 85 of this Department (E. S. R., 10, p. 678).

Sugar as food, MARY H. ABEL (*British Food Jour., 1 (1899), Nos. 10, pp. 297–298; 11, pp. 328–331; 12, pp. 361–365*).—A reprint of Farmers' Bulletin 93 of this Department (E. S. R., 11, p. 278).

Two forms of apparatus for regulating and measuring the work performed by man, N. ZUNST (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, No. 3–4, pp. 372–375, fig. 1*).—The author describes two forms of apparatus for regulating and measuring work performed by man. Such apparatus is called a bremsergometer.

Food—nutrients—food economy (*U. S. Dept. Agr., Office of Experiment Stations Circ. 43, p. 6*).—Summarizes briefly a number of the general principles of food and nutrition.

Analyses of feeds, A. L. WINTON, A. W. OGDEN, and W. L. MITCHELL (*Connecticut State Sta. Rpt. 1898, pp. 308, 309*).—The composition of Blatchford's calf meal, Chicago gluten feed, H. O. dairy feed, Quaker oat feed, and chaff is reported. A brief note is given of the examination of 2 samples of wheat flour. One was found to consist wholly of wheat; the other contained a large quantity of cornstarch. The value of commercial mixed feed is discussed.

Concentrated feed stuffs, J. B. LINDSEY (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 77–86*).—The more important concentrated feeding stuffs are described, the laws regulating the sale of feeding stuffs in various countries and States are quoted, as well as the experiences of the first year in Massachusetts under the State law on this subject.

Fodders and feeds, L. A. VOORHEES and J. P. STREET (*New Jersey Stas. Rpt. 1898, pp. 101–121*).—Analyses are reported of rye and crimson clover, imported crimson clover, Japan broom-corn millet, Japan millet, soy beans, green soy beans, barley and peas, cowpeas, corn fodder, oats and peas, Canada field peas, corn, corn stover, shelled corn, corncobs, waste corn fodder, cornstalks, corn silage, mixed hay, rice meal, oats, wheat bran, dried brewers' grains, undigested corn, cotton-seed meal, undecorticated cotton-seed meal, old process linseed meal, Cleveland flax meal, gluten meal and feed, and prepared feeds (Quaker oat feed, H. O. dairy feed, H. O. horse feed, and Blatchford's calf meal). Many of these analyses were made in connection with experiments conducted at the station.

Among other topics, a discussion of the composition, adulteration, and inspection of feeding stuffs is reprinted from Bulletin 131 of the station (E. S. R., 10, p. 977), as well as the market price of a number of commercial feeds. The article also includes a compilation of average analyses of the more important fodders and feeding stuffs.

The value of molasses as a food for farm animals (*Landtm. Månadsbil., 1899, No. 7, pp. 97-101*).

Concerning the phosphorus of muscular tissue, J. J. R. MACLEOD (*Ztschr. Physiol. Chem.. 28 (1899), No. 5-6, pp. 535-558*).—From a number of experiments the author draws the following conclusions: The amount of phosphorus of organic compounds in the aqueous extract of muscular tissue is much diminished by muscular work, while the amount of phosphorus of inorganic compounds is correspondingly increased. Intense muscular exertion diminishes the nucleon-phosphorus in the aqueous extract of muscular tissue, and there is an especially noticeable decrease of the organic compounds containing phosphorus which are not contained in the nucleon.

Influence of large quantities of water upon the excretion of nitrogen by man, R. O. NEUMANN (*Arch. Hyg., 36 (1899), No. 3, pp. 248-263, table 1*).—A number of experiments are reported which, in the author's opinion, show that the consumption of large quantities of water did not cause a permanent increase in the amount of nitrogen excreted and that, accordingly, it is proper to assume that there was no increase cleavage of protein.

The influence of nutrients in restoring exhausted muscle, J. FRENTZEL (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, No. 3-4, pp. 383-388*).—Experiments with two men were made in which a Mosso ergograph was used. The author concludes that protein restores exhausted muscle in about the same time as sugar and that the restoring value of protein is quantitatively larger than that of sugar. Experiments on the value of fat for restoring exhausted muscle are also briefly noted, as well as a number of observations on the time which elapses before nitrogen consumed is recovered in the urine.

Note on the metabolism of ruminants, O. HAGEMANN (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. pt. 2, p. 382*).—This is a note regarding some of the calculations in the article abstracted above (p. 772).

The fate of proteid materials when introduced into the circulatory system, I. MUNK and M. LEWADOWSKY (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Supt. pt. 1, pp. 73-88*).—A number of experiments are reported.

Metabolism experiments with edestin, R. LEIPZIGER (*Arch. Physiol. [Pflüger], 78 (1899), No. 7-8, pp. 402-422*):—A number of experiments with dogs are reported. The edestin used was prepared from hemp seed according to Osborne's method. The balance of income and outgo of nitrogen, phosphoric acid, calcium, and magnesium was determined.

Amylaceous digestion in the stomach of carnivora, H. FRIEDENTHAL (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. pt. 2, pp. 383-390*).—According to the author, his experiments show that soluble starch, ethero dextrin, and very small quantities of maltose are formed by the diastatic ferment, but carbohydrates undergo no other change in the stomach of dogs.

The excretion of borax, E. ROST (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. pt. 2, pp. 568-570*).—From experiments which are briefly described, the conclusion is drawn that rabbits excrete borax from the mucous membrane of the digestive tract when it has been introduced intravenously and subcutaneously. The article contains a number of references to similar investigations.

The influence of thein upon the excretion of alkalis in urine, I, K. KATSUYAMA, T. KUWAHARA, and K. SENO (*Ztschr. Physiol. Chem., 28 (1899), No. 5-6, pp. 587-594*).—From a number of experiments with rabbits, the authors conclude that, together with an increased excretion of urea, thein induces an increased excretion of the alkali of the urine.

Annual reports of the live stock associations of the Province of Ontario, 1898-99 (*Toronto: Ontario Dept. Agr., 1899, pp. 169*).—This contains the usual statistics and reports.

An investigation of the (Privislyansk) Russian Polish horned cattle, N. LOUCHNIK (*Selsk. Khoz. i Lyesov., 194 (1899), Sept., pp. 401-443*).—The author points out that the cattle raised in Russian Poland are of inferior breed and discusses the reasons for this.

Sheep-fattening experiments, 1898–99, J. GRUDE (*Aarsber. Offent. Foranst. Landbr. Fremme, 1898, pp. 292–304*).

Purchased feeding stuffs consumed [by sheep pastured] on grass (*Rpt. Agr. Expts., Cornwall, County Council, 1898, p. 49*).—A brief note on experiments on the value of different feeding stuffs for supplementing pasturage. Four plats were used; 18 sheep were fed on each plat 31 days and 8 sheep 52 days. Linseed cake was fed on plat 1, decorticated cotton-seed cake on plat 2, and maize on plat 3. The sheep on plat 4 consumed no grain in addition to pasturage.

"With the experience of 2 seasons only to guide us it would be decidedly premature to express a definite opinion on the respective manurial residues of these feeding stuffs. Nevertheless it is a curious fact that among landowners and farmers of experience who have inspected the plats there is complete unanimity of opinion as to the results. The plat upon which linseed cake is consumed is very closely grazed and is given the first place. Between maize and cotton cake the difference is very trifling, but the difference between the plat upon which no feeding stuffs are consumed and the 3 foregoing is becoming marked."

The Anglo-Norman horse, A. GALLIER (*Le cheval Anglo-Normand. Paris: J. B. Baillière & Sons, 1900, pp. 320, ill.*).—The origin, history, and value of the Anglo-Norman horse is discussed, as well as the value of this breed and methods of encouraging the breeding of these horses.

Native Russian races of horses, S. P. URUSOV (*St. Petersburg: Min. Agr. and Imp. Domains, 1899, pp. 111; rev. in Selsk. Khoz. i Lyesov., 195 (1899), July, pp. 181, 182*).—A report to the Imperial Department of Agriculture.

A portable poultry house (*Queensland Agr. Jour., 5 (1899), No. 6, pp. 562, 563, pl. 1*).—A poultry house suitable for housing poultry in a large run in stubble fields is described.

DAIRY FARMING—DAIRYING.

Some of the factors determining the richness of milk, C. D. SMITH (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 152–155*).—Records of a herd of some 25 cows at the Michigan Station for 5 years and of 8 cows at the New York State Station are summarized and used in a discussion of variations in the composition of milk during successive periods of lactation, from month to month in the same period, during different seasons of the year, and from day to day. The following conclusions are reached:

"(1) A cow yields as rich milk as a heifer as she will as a mature cow. . . .

"(2) The milk is as rich in the first month of the period of lactation as it will be later, except perhaps during the last few weeks of the milk flow, when the cow is rapidly drying off.

"(3) There is little difference in seasons as to the quality of the milk. Milk, while the cows are at pasture, is neither richer nor poorer, on the average, than the milk yielded when the cows are on winter feed.

"(4) The milk of a fair-sized dairy herd varies little in composition from day to day. Radical variations in this respect should be viewed with suspicion, as indicating either mistakes in testing or gross mismanagement of the herd."

Can the brain and nervous system of a cow affect her yield of butter fat? J. H. SHEPPERD (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 185–193*).—In a discussion of this subject the author reports 2 experiments conducted by himself, and reviews a number of experiments made at various stations relative to the effect of change of milkers, change of quarters, and frequent milking.

In the first experiment by the author a comparison was made of the amount of milk drawn from a cow by a man and a calf, both beginning at the same time, and each milking two teats. The difference in the weight of the calf before and after milking was taken as the quantity of milk drawn by the calf. The experiment lasted 6 days, during which the calf obtained 2.8 lbs. more milk than the man under the same conditions. The second experiment was a comparison of 3 milkers. The trial lasted 4 weeks and included 3 cows. The change in milkers was made every 2 or 3 days. Considerable differences were observed in the yields of milk and fat obtained by the different men.

Theories accounting for the results obtained in the author's experiments and for the effects due to change of milkers, change of quarters, and frequent milking in the cases cited are presented. The data are considered as satisfactorily explained on the theory that the brain and nervous system of the cow can affect the yield and composition of her milk.

Comparison of mixed grain and Indian corn for dairy cows, F. FRIIS ET AL. (*15. Rpt. K. Vet. Landbohöjskoles Lab. Landökon Forsög* [*Copenhagen*], *1899, pp. 171*).—The report gives a full account of the eleventh and twelfth years' cooperative feeding experiments conducted under the direction of the State Danish Experiment Station. In both these years Indian corn was compared with barley and oats, the common grain feeds for milch cows in Denmark. The experiments were conducted according to the same general plan as earlier ones (E. S. R., 9, p. 983). Seven estates took part in the work in both years, and furnished 264 cows in 1898 and 241 in 1899 for the experiments. The rations of the cows were the regular rations of the estates during the preparatory and post-experimental periods, the grain fed in all cases consisting of one-half barley and oats and one-half corn. During the experimental period proper lot A received barley and oats only, while lot C received corn only, and lot B received the mixture of barley, oats, and corn. The corn and mixed grain were fed against each other, pound for pound. In addition to these materials all the lots received the same amount of oil cakes, mangels, and hay, and straw *ad libitum*. The quantities of corn and mixed grain that replaced each other varied on the different estates from 1½ to 3 lbs. (Danish) daily per cow, and this constituted from one-half to two-thirds of the total concentrated feed. The results obtained as regards the fat content of the milk showed only insignificant differences, on the average, for all herds.

The small differences were in favor of the mixed grain, but too small to have any practical importance, being within 0.1 per cent. The same was true of the results of the complete chemical analyses.

As regards the quantities of milk yielded by the different lots, the corn-fed lots produced, on the average, slightly more milk. There was a small gain in milk of lot C (corn only) over the average yields of either lot A (mixed grain only) or lot B (mixed grain and corn, half and half). The production of butter fat was, however, almost identical for the different lots, with a tendency toward lower results for corn (average daily yields per head: 0.724, 0.723, and 0.722 lb. for lots A, B, and C, respectively).

The weighings made of the cows at the different periods of the experiment showed that the corn-fed cows increased slightly more in live weight than either of the two other lots, the increase per head per day for the 3 lots being 0.21, 0.25, and 0.33 lb., respectively. The consumption of straw was not influenced by the kind of grain fed.

Influence of corn on quality of butter.—The keeping quality of the butter produced on two of the estates participating in the experiments was ascertained by the method adopted in the scoring of butter at the Permanent Danish Butter Exhibitions, the butter being scored twice, a few days after it was made and again 14 days later. The butter produced by the corn-fed cows scored somewhat higher and kept slightly better than that from the two other lots. The analyses of the butter fat showed that the iodin number and the refractive index were increased to some extent by the corn feeding, and the volatile fatty acids were changed in a similar manner as when oil cakes were fed (E. S. R., 9, p. 490). The churning temperature of the cream from the corn-fed cows lay somewhat lower (0. 7 to 1.1° F.) than that from the other lots, with other churning factors the same.

Influence of sugar-beet pulp on quality of butter.—The effect of sugar-beet pulp on the quality of the butter produced was studied in an experiment at Egeskov estate during 1898–99 with 30 cows, separated into 3 lots. Lot A received 25.4 lbs. of mangels, lot B 30.5 lbs. of beet pulp, and lot C 61.0 lbs. of pulp, the feed being otherwise similar for all lots, with the exception that the allowance of mixed grain for lot C was reduced by 2.5 lbs. on account of the heavier pulp feeding.

The first scoring of the butter showed that produced by lot B to be of slightly better and that produced by lot C of slightly lower quality than the butter from lot A (mangels), while the second scorings showed that the keeping quality of the butter from all lots was similar. The churning time was 4½ minutes longer, on the average, for lot C than for lot A, and the end temperature of the churning 0. 7° F. higher than that for lot A, with other factors similar. The determinations of iodin number and refractive index failed to show any difference between the butter produced by the different lots, while the pulp-feeding evidently decreased the volatile fatty acids by 1 to 2 cc. (lot A, 33.9; lot B, 32.6; lot C, 32.0 cc.).—F. W. WOLL.

The influence of pasturage on the fat content of milk, K. P. KJÄRSGAARD (*Mälkeritid., 12 (1899), No. 18, pp. 319–321*).—The fat content of the milk of 19 different Danish herds of dairy cattle was determined before and after the cows were turned to pasture in the spring. The first series of determinations was made between April 25 and May

19, the second 20 days later, and the third 40 days after the latter. The size of the herds ranged from 4 to 99 cows, the average being about 33 cows. The average results obtained for all herds are shown below:

Fat content of milk before and after turning cows to pasture.

	Average.	Range.
	Per cent.	*Per cent.*
On winter feed	3.33	3.09–3.56
On pasturage, first test	3.67	3.23–4.04
On pasturage, second test	3.60	3.34–3.97

The first set of determinations gave higher results on pasture in case of 10 herds, and the second set in case of 7 herds, while 1 herd showed the same fat content on winter feed and first time on pasturage, and 1 herd showed the same fat content both times on pasturage. In no case was a higher fat content found when the cows were on winter feed than when at pasturage.—F. W. WOLL.

On the effect of pasture on the yield and quality of milk, F. FRIIS (*45. Rpt. K. Vet. Landbohöjskoles Lab. Landökon Forsög* [*Copenhagen*], *1899, pp. 57–65, 88–93*).—The cow-feeding experiments conducted by the Danish State Experiment Station during the past 10 years have always been continued until after the cows were let out to pasture in the spring. Experiments of this kind have been conducted on 8 different estates, 4 to 8 each year, and included 1,961 cows in all. The results have been compiled by the station and are presented in full in the report. The milk yield and percentages of fat and total solids have been calculated for each estate and for each year for 3 ten-day periods immediately preceding and following the tying out at pasture. The average results obtained for all cows included in the experiments are shown in the following table:

Effect of pasture feeding on milk yield.

Year.	Number of estates.	Yield of milk per cow daily.						Fat content of milk.					
		Winter feeding.			Pasture feeding.			Winter feeding.			Pasture feeding.		
		Period 3.	Period 2.	Period 1.	Period 1.	Period 2.	Period 3.	Period 3.	Period 2.	Period 1.	Period 1.	Period 2.	Period 3.

1899	5	21.2	20.7	19.9	21.6	21.7	20.5	3.07	3.05	3.11	3.42	3.32	3.23
Average	....	21.2	20.7	20.2	21.7	21.7	20.3	3.15	3.18	3.21	3.47	3.34	3.30

The highest yields of milk after the cows were let out in some years came during period 1 and in others during period 2; the weather may have been the deciding factor in bringing about this result. The average for all years and series of experiments was 21.7 lbs. for both periods.

The composition of the milk, calculated as shown in the preceding table, was as follows:

Average composition of milk on winter feeding and pasturage.

	Winter feeding.			Pasture feeding.		
	Period 3.	Period 2.	Period 1.	Period 1.	Period 2.	Period 3.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Total solids	11.87	11.91	11.95	12.37	12.27	12.23
Solids-not-fat	8.72	8.73	8.74	8.90	8.93	8.93

While the fat content of the milk after 30 days on pasturage had gone down to where it would have been if the cows had been in the stable and the percentage of fat had continued to increase in the same ratio as during the last 30 days of stable feeding, the total solids content was not decreased to a similar extent. The results of the complete chemical analyses of the milk during one year indicate that this is due to an increase in the percentage of nitrogenous components in the milk, since both the milk sugar and ash remained nearly uniform before and after the cows were let out.

It should be observed that all animals included in these experiments were fall-calving cows; the results obtained do not, therefore, necessarily apply to spring-calving cows, or to cows that are farther removed from the drying-off stage than these cows were during the last ten-day period on pasturage.—F. W. WOLL.

Dairy husbandry, C. B. LANE (*New Jersey Stas. Rpt. 1898, pp. 205-226*).—Conclusions from three years' work upon the cost, yield, and feeding value of various forage crops are reprinted from Bulletin 130 of the station (E. S. R., 10, p. 946); and an account is given of dairy work during the year, including the growing of various soiling crops, a study of the character of the refuse from the feeding of cornstalks, experiments upon the relative feeding value of whole and ground corn, data on the cost of milk production, and a record of the dairy herd.

A large number of soiling crops were grown in different rotations on acre plats. These furnished green fodder for 25 cows from May 1 to October 5. Tables show the cost of production, yield, arrangement, and the amount of nutrients furnished by each crop. Brief notes are given on the growth of the different crops. Eight tons of green forage was secured from 2 cuttings of alfalfa. Further experiments are considered necessary to determine the value of vetch as a soiling crop. Spring rye grown with peas showed no advantage over oats.

Determinations were made of the amount and composition of the portion of cornstalks remaining uneaten when fed to stock. During an experiment lasting 10 days one cow was fed 200 lbs. cornstalks, of which 60 lbs. remained uneaten. Analyses of the cornstalks and refuse and the digestible nutrients in the portions fed, wasted, and eaten in the experiment are given. From the data obtained the author computes a balanced ration made up of 20 lbs. cornstalks and 3 lbs. each of wheat bran, dried brewers' grains, corn meal, and linseed meal.

"The results of this experiment show very strongly the advantage in using a silo. At least $\frac{5}{6}$ of the 30 per cent waste in feeding dry cornstalks, as indicated in the experiment, could be prevented by using a well-built silo; besides, 12 per cent more milk could be produced from the silage than from the dried stalks."

Whole corn and corn-and-cob meal, in rations otherwise alike, were fed to 2 cows, one in the fifth and one in the tenth month of lactation. The test covered 2 periods of 12 days each, with a preliminary period of 5 days and a transition period of 5 days, when the rations were reversed. The yield of milk was 9.3 per cent greater and the yield of fat 4.9 per cent greater from the meal ration. There was also a slight increase in the weight of the animals when fed the meal ration. The results are attributed to the greater digestibility of corn-and-cob meal as compared with whole corn. It is estimated that the feeding value of a ton of corn is $2 greater when fed in the form of meal than when fed whole, deduction being made for the additional cost of husking and grinding. Determinations showed that 57.3 per cent of the corn fed on the ear passed through the alimentary tract undigested.

The cost of milk production for the year ended April 1, 1898, is given. The herd averaged 25 cows for the year.

"The average cost of the daily ration was 11.44 cts. of which 5.06 is due to purchased feeds and 6.38, or 56 per cent, to the cost of farm foods. The cost of food per quart of milk is shown to be 1.47 cts. of which 0.65 ct. is due to purchased feeds and 0.82 ct. to farm crops. . . .

"The cost per hundred [including the cost of labor and the interest on and decrease in the value of the herd] was $1.10. At $1 per hundred, the price received in rural districts, the profits from the business, if any, must be in the manure. In the calculation of the cost of farm foods, the manure was charged at the rate of $1.50 per ton, and the amount produced by the herd during the year was 274 tons.

"In selling milk for $1 per hundred, the receipts are $154.77 less than the expenses. Deducting this amount from the actual charges made for the manure in the growing of the crop, $1.50 per ton, there remains $256.23, which represents the profits from 25 cows—an amount too small to make the business pay.

"At 3 cts. per quart, the price that could have been received at wholesale, the receipts would amount to $2,129.70; deducting the cost of purchased feeds, hay and interest and decrease in value of herd, amounting to $1,187.12, we have a balance of $942.58, which represents the value of the home-grown produce, or, in other words, at 3 cts. per quart, the farm would sell its home-grown produce to the dairy at profitable prices, viz, $2.50 for soiling crops, $5.05 for silage, and $8 per ton for dried corn stover, a gain on the crops over cost of production of $1.10 per ton for soiling crops, $2.60 for silage, and $3 for dried corn stover, besides an additional gain represented by the 274 tons of manure."

A table shows the amount of fertilizing elements contained in the feeding stuffs purchased and in the milk produced by the herd of 23 cows in 1896 and 25 cows in 1897. During the two years the excess of nitrogen, phosphoric acid, and potash in the feeding stuffs purchased over the quantities in the milk sold from the farm was 1,705, 1,401, and 505 lbs., respectively.

The record of 26 cows remaining in the herd throughout one year, ended April 1, 1898, is given.

Records of best and poorest cows for milk and butter production.

	Animal yield.	Value of product.			Cost of feed.	Gain over cost of feed with—		
		Milk at 1 ct. per lb.	Milk at 3 cts. per qt.	Butter at 20 cts. per lb.		Milk at 1 ct. per lb.	Milk at 8 cts. per qt.	Butter at 20 cts. per lb.
Milk production:	*Pounds.*							
Best cow	9,148	$91.48	$125.88		$41.76	$49.72	$84.12	
Poorest cow	4,189	41.89	57.65		41.76	.13	15.89	
Average cow	6,143	61.43	84.54		41.76	19.67	42.78	
Butter production: *a*								
Best cow	442			$88.40	41.76			$46.64
Poorest cow	238			47.60	41.76			5.84
Average cow	318			63.60	41.76			21.84

a Calculated.

"The tabulation shows that the best cow pays for her feed and $46.64, in addition to skim milk and manure to represent the care and profits, while the manure and skim milk of the poorest cow, in addition to $5.84, represent the pay received for her care and the labor of making the butter. The facts brought out by the above records indicate that there is but little profit derived from a cow that does not produce 200 lbs. per year, and points to the necessity of careful selection of animals for the butter dairy."

The average waste per month during the year from handling, cooling, bottling, and delivering the milk was 9.3 per cent.

The white blood corpuscles in milk and Storch's test for pasteurized milk, C. BARTHEL (*Nord. Mejeri-Tidn.*, *14* (*1899*), *No. 16*, *p. 215*).—The author states that cows' milk contains normally large numbers of leucocytes, and attributes the reaction obtained in dairy products with peroxid of hydrogen (E. S. R., 10, p. 384) to their presence. Leucocytes appear in the greatest abundance in separator slime and can be readily observed there under the microscope by staining with hæmatoxylin, which will show numerous nuclei of the leucocytes. It is also possible, the author says, that some of the cell nuclei thus observed are derived from torn epithelial cells of the alveoli of the milk glands. Cream is richer in leucocytes than skim milk, which in the author's opinion is due to the adhesion of leucocytes to the fat globules by which they are carried over into the cream.

The author considers the leucocytes, or an enzym secreted by them, the cause of the phenomena observed by Babcock and Russell and by them attributed to a special unorganized ferment called galactase. Aside from the similarity in the behavior toward Storch's test, the leucocytes are said to behave toward anæsthetics in the same manner as galactase. Formalin, carbolic acid, and corrosive sublimate destroy their action, while chloroform, ether, and benzol are stated to have no influence in this direction. Another indication that the color reaction obtained in Storch's test is due to the presence of leucocytes is that whey gives a reddish brown, and not a blue color, as in case of milk. The latter color has been shown by Storch to be due to the casein of the milk. Blood serum treated with paraphenylendiamin and peroxid of hydrogen will also give a reddish-brown color.

The property to decompose H_2O_2 is, however, one common to all protoplasmic substances, and not to fibrin or enzyms alone, provided it has not been destroyed by heat or special reagents. If leucocytes obtained from blood that has been entirely freed from plasma by washing with ice-water, are added to milk previously heated above 80° C., the blue color will appear in the peroxid test; the same test will, however, be obtained if blood serum prepared by filtering through a Chamberland filter is added to heated milk.—F. W. WOLL.

The preparation of cream and butter free from injurious microorganisms, K. B. LEHMANN (*Arch. Hyg., 34 (1899), No. 4, pp. 261–271*).—In 6 experiments the cream separated by a hand separator was found to contain approximately twice as many germs in 1 cc. as the milk from which it was derived. The process of butter making, it is said, does not destroy these germs. The dangers from these sources are pointed out. Experiments in pasteurizing the fresh cream by heating for 10 minutes at 80° C. were unsuccessful, but this is attributed to the apparatus. With the use of a simple stirring apparatus the pasteurization for 10 minutes at 85° was found sufficient, reducing the germ content to about 0.1 per cent of the original.

The control of a commercial cream-pasteurizing plant for about 8 months showed that heating for 10 minutes at 85° C. reduced the germs from about 10,000,000 to 7,000 per cubic centimeter except in the very hot weather. The author considers that the hygienic requirements were practically fulfilled. The cream had an agreeable cooked taste, similar to burnt almonds, kept 48 hours except in hot weather, and was readily churned, either sweet or sour.

Bacillus typhi abdominalis in milk and butter, H. L. BOLLEY and M. FIELD (*Proc. Soc. Prom. Agr. Sci., 1898, pp. 168–175*).—The biological characters of the typhoid bacillus and the sources of milk contamination with this germ are discussed, and investigations to determine the persistence of typhoid germs in milk and its products are reported.

During 1897 and 1898, 248 separate experiments in inoculating dairy products with typhoid germs were made. A table gives the data for 23 of these experiments considered as giving results of undoubted accuracy. A sample of butter salted at the rate of 1 oz. to the pound and another sample salted at the rate of 4 oz. to the pound were inoculated with typhoid germs in small pits in the butter where the buttermilk had collected. The germs multiplied but did not spread into the surrounding butter. Cultures made at the end of 7 days from butter at the margin of one of these pits proved fatal to guinea pigs when inoculated into the body cavity. In only 1 out of 8 experiments reported did typhoid germs survive for a longer period than 10 days in butter which had been thoroughly infected. No marked growth of the germs was observed in samples from which the buttermilk had been thoroughly worked out. Typhoid germs remained alive for several months in cream and in the buttermilk and unsalted butter from the infected cream. In experiments with sweet milk the results are considered as adding nothing to previous work. The germs developed in great numbers and the milk became acid but did not coagulate. In mixed infection the typhoid germs were not outgrown and in some cases became predominant.

The part played by lactic-acid bacteria in the ripening of cheese, E. VON FREUDENREICH (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 8, pp. 240–249*); and H. WEIGMANN (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 18–19, pp. 630–641*).—The first paper is largely a controversial article in which the various theories of the cause of the ripening of cheese are reviewed, and especially the views of Weigmann expressed in a previous article (E. S. R., 10, p. 592) are combated. An additional series of experiments is given with milk inoculated with a number of forms of lactic-acid bacteria, chalk being added to neutralize the acid produced. With some forms a considerable decomposition of the casein was indicated by the analysis. One of the most active forms had previously been found in a number of samples of natural rennet.

The author explains that he has worked only with hard cheese, while Weigmann used soft cheese. He fails to find any anaerobic bacteria in Emmenthaler cheese. He has verified Babcock and Russell's discovery of an unorganized ferment in milk and believes that it may play a part in the ripening of cheese. He suggests that the ferment may prepare the casein for the action of the lactic-acid bacteria by dissolving it.

In the second paper Weigmann gives some additional experiments which he holds show that lactic-acid bacteria do not play the principal part in ripening, even in hard cheese (Tilsiter), as a number of other forms were found.

In further experiments the effects of lactic-acid bacteria, *Clostridium licheniforme*, *Paraplectrum fœtidum*, *Oïdium lactis*, *Penicillium*, and *Mucor mucedo* were studied. After preliminary trials these were used in different combinations in milk cultures. It was found that both of the molds have a very powerful peptonizing action and that Johan-Olsen was right in including them in the list of cheese-ripening organisms. They also give a flavor to the cheese.

The author believes that all of the bacteria found in milk work together, partly simbiotically and partly metabiotically, the lactic-acid bacteria first preparing the material for the growth of the others, the molds and the various coli bacteria taking care of the lactic acid formed and at the same time peptonizing the casein and producing flavors, and the bacteria of the class of Paraplectrum and Clostridium giving the cheese the characteristic odor and taste. The character of the cheese will depend upon the proportion in which these organisms are present, which in turn will depend upon the method of making.

Practical experiments in making Tilsiter cheese are then reported, in which mixtures of the organisms mentioned above were used, the proportions being given as nearly as practicable. The results show that the ripening was best when the whole category of organisms was present.

The author questions whether, when all of the cheese-ripening organisms have been discovered and the relative proportions for different kinds of cheese worked out, it will be possible to entirely exclude the action of the organisms remaining in the milk (even after pasteurization) or gaining access during the process of cheese making. He suggests that the effect of the milk and the place of manufacture will still be apparent, and points out that the matter is not as simple as in the case of cream ripening, which occupies only a short time.

A study of the bacterial flora of Roquefort cheese, GRIMM (*Selsk. Khoz. i Lyesov., 194 (1899), July, p. 27*).—A preliminary account of this investigation, which is not yet completed. The following results have been obtained: The green particles which permeate the ripe cheese are aggregates of spores of *Penicillium glaucum*, which thus appears to be a specific constituent of this cheese and which imparts to it its peculiar taste. The poisonousness of *Penicillium glaucum* explains why the extensive use of this cheese as food is injurious. Further, a new lactic-acid bacillus has been separated which is not identical with the lactic-acid bacilli of Heuppe, Leichmann, and Weigmann. The transformation of milk sugar into acid under the influence of this bacillus takes place more rapidly than under the influence of *Bacillus acidi lactici*.—P. FIREMAN.

Annual reports of the cheese and butter associations of the Province of Ontario, 1898 (*Toronto: Ontario Dept. Agr., 1899, pp. 192, figs. 5*).—This contains the proceedings of the annual meetings of the associations, including a large number of popular articles, and an appendix giving a list of members and officers of the associations and a financial statement.

Report of the dairy institute at Proskau for 1898–99 (*Bericht über die Thätigkeit des Milchwirthschaftlichen Instituts zu Proskau für das Jahr vom 1. April 1898 bis 1. April 1899. Oppeln: Joseph Wolff, 1899, pp. 25; abs. in Milch Ztg., 28 (1899), No. 38, pp. 598, 599*).—A general report on educational and experimental work and on the production of butter and cheese at the institute.

Report of the State dairy agent in Manchester, England, for 1898, H. WEDIN (*Meddel. K. Landtbr. Styr., 1899, No. 52, pp. 75*).

Recent progress in dairying, P. DE VUYST and P. WAUTERS (*Nouveaux progrès en laiterie. Louvain: A. Uystpruyst, 1899, pp. 81, figs. 49*).—Contains a general review of recent inventions in dairy apparatus and of investigations along different lines of dairy work, an account of cooperative dairying and dairy associations in different countries, and of instruction in dairying in Belgium, and a list of some of the more recent dairy publications.

The Ayrshire cow, J. STEWART (*Queensland Agr. Jour., 5 (1899), No. 6, pp. 546–548*).—A brief discussion of the origin of Ayrshire cattle, with notes on their care, management, etc.

Is the weight of cows of influence on the profitableness of dairying? (*Molk. Ztg., 13 (1899), No. 35, p. 545*).—Cows weighing between 1,000 and 1,300 lbs. are considered in general the most profitable.

The truth regarding the spaying of milch cows, ELOIRE (*Progrès Vét., 1898; abs. in Deut. Thierärztl. Wchnschr., 7 (1899), No. 15, p. 141*).—All of the cows of a large and well managed dairy failed to get with calf during an entire year, owing to the impotency of the bull; but notwithstanding this, the cows continued to give milk for nearly 2 years in the same manner as if they had been spayed. Had these cows been spayed after calving the prolonged lactation, the author says, would have been credited to the operation. He admits that spayed cows tend to get fat, provided the lactation is not prolonged.

How can a large yield of milk of good quality be secured? A. STUTZER (*Wie erhalten wir viel Milch von guter Beschaffenheit? Leipsic: Hugo Voigt, 1899, pp. 122*).—This is a second edition of this popular pamphlet on the principles of feeding milch cows, the effect of food on yield and composition of milk, and the personal equation of the cow herself. The author concludes that the latter is a factor of great importance.

The production of milk and butter in Denmark, B. BOGGILD (*Ugeskr. Landm., 44 (1899), No. 47, pp. 585–587*).—The number of creameries in Denmark in 1897 was 1,145, which produced a total of 127.7 million lbs. of butter and 20.96 million lbs. of skim-milk cheese. The average price received at the factory for the products were: butter, 21.5 cts. per pound; cheese, 3.5 cts. per pound. Assuming that the above quantity of butter represents nine-tenths of the butter production of the country, the total production was 141.93 million lbs., or about 133 lbs. of butter per cow. The per capita consumption of butter (and oleomargarine) is calculated to approximate 30 lbs., or at the highest estimate 33 lbs. The production of milk is estimated at 4,958.6 million lbs., or about 4,620 lbs. per cow and 2,200 lbs. per capita.—F. W. WOLL.

Accounts of 27 cooperative creameries in Holbäk Amt, Denmark, S. MADSEN (*Mälkeritid., 12 (1899), No. 27, pp. 455–467*).—The article gives detailed information concerning the different phases of the business of 27 Danish cooperative creameries, number of patrons and cows, equipment, milk and butter account, losses, fat content of skim milk, expense account, total and per 1,000 lbs. of milk received, gross and net receipts, etc.—F. W. WOLL.

Water content of butter made in the Province of Posen, TIEMANN (*Chem. Ztg., 23 (1899), No. 78, p. 942*).—The range observed (number of samples not given) was from 8.69 to 19 per cent, the average being 12.88 per cent.

Analysis of butter from reindeer milk, F. H. WERENSKIOLD (*Aarsber. Offent. Foranst. Landbr. Fremme, 1898, p. 120*).—The sample contained 8.48 per cent water, 86.80 per cent fat, 2.01 per cent protein, 1.87 per cent ash, and 0.84 per cent other substances. The specific gravity of the fat at 100° C. was 0.8653, the refractive index at 45° C. was 38°, the melting point 35 to 40.5°, solidification point 37 to 40°, iodin number 22.85, saponification number 228.5, and Reichert number 27.0.—F. W. WOLL.

Contributions on the spontaneous souring of milk, Y. KOZAI (*Abs. in Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 18–19, p. 660*).—The article deals with the kind of lactic acid produced by different bacteria and under varying conditions of temperature, nutrition, etc.

Possibility of distinguishing between raw and cooked milk by chemical reagents, TIEMANN (*Chem. Ztg., 23 (1899), No. 87, p. 942*).—The author has verified the reliability of Storch's tests (hydrogen peroxid and phenylendiamin; E. S. R., 10, p. 384). Milk which had been heated to 75° C. or above gave the reaction, and the reaction was also produced when a small quantity of heated milk was added to raw milk.

Determination of dirt in milk, H. HÖFT (*Molk. Ztg., 13 (1899), No. 35, p. 546*).—The determination of dirt in milk by means of a centrifugal apparatus is described.

Regulations for the sale of milk (*Milch Ztg., 28 (1899), No. 33, pp. 513–515*).—Proposed uniform regulations for the sale of milk in the larger cities of Prussia.

Regulations governing the sale of milk in Saxony (*Milch Ztg., 28 (1899), No. 35, p. 551*).

Law relating to the pasteurization of milk in Denmark (*Milch Ztg., 28 (1899), No. 47, pp. 744, 745*).—Observations on the working of this law, which went into effect June 1, 1899.

Investigation of cream, its specific gravity, fat content, and the yield of butter from same, N. GRIPENBERG (*Nord. Mejeri Tidn., 14 (1899), Nos. 26, pp. 352–354; 27, pp. 367, 368*).

Tuberculosis and milk, J. I. TORRALBAS (*An. Acad. Cien. Med., Habana, 36 (1899), No. 431, pp. 117–121*).

On the occurrence of tubercle bacilli in oleomargarine, MORGENROTH (*Hyg. Rundschau, 9 (1899), No. 10, p. 481*).—A preliminary communication. It is stated as the result of investigation that virulent, true tubercle bacilli not infrequently occur in oleomargarine and that it is quite as important as in the case of butter to stipulate that it shall come into the market free from tubercle bacilli.

On the occurrence of tubercle bacilli in oleomargarine, MORGENROTH (*Hyg. Rundschau, 9 (1899), No. 22, pp. 1121–1135*).—Ten samples of oleomargarine were taken, of both cheaper and more expensive grades. These samples were melted at a temperature of 42 to 50° and treated in a hand centrifuge for 5 minutes. The fat was poured off and the remainder, after being diluted with sterile water, was used for inoculation experiments. Four animals were inoculated with material from each sample. Of the 10 samples 8 were found to be infected with living tubercle bacilli.

Report of the third general Swedish Cheese Exhibition and Dairymen's Convention in Stockholm, 1899, K. F. LUNDIN (*Stockholm, 1899, pp. 92*).

Faults, errors, and losses in cheese making, G. S. THOMSON (*Jour. Agr. and Ind., South Australia, 3 (1899), No. 5, pp. 435–439, fig. 1*).—Includes descriptions of the acid test and the Wisconsin curd test.

Belgian regulations for manufacture and sale of cheese (*U. S. Consular Rpts., 1899, No. 231, p. 634*).

Observations concerning cheese diseases and their remedies, F. BAGGE (*Tidskr. Landtmän, 20 (1899), No. 15, pp. 264–269*).

VETERINARY SCIENCE AND PRACTICE.

The local distribution of tubercle in various species, with reference to the channel of infection, W. HUTCHINSON (*British Med. Jour., 1899, No. 2028, pp. 1350–1352*).—The observations which the author reports in this paper were made chiefly in the London zoological gardens. About 80 *post-mortem* examinations were made upon a considerable variety of mammals and birds. Among the mammals may be mentioned kangaroos, antelopes, armadillos, jackals, llamas, rodents, lemurs, monkeys, and apes. From the examinations which were made it is concluded that in mammals the disease kills almost invariably by the lung. It was noticed that although the lung infection produced the most serious effects upon the animal, yet in only 6 out of 40 cases in mammals was the disease confined to the lungs, and in 7 cases it was confined entirely to the abdomen. In cattle, antelopes, sheep, and gazelles the disease shows a marked preference for the pleura and pericardium. Purulent degeneration of the tuberculous masses seems to be much less frequent in animals than in man.

In birds, on the other hand, the lungs are rarely affected by tuberculosis. The chief seat of the disease in birds is in the abdominal viscera, more especially the liver, spleen, and wall of the intestines. In only 20 per cent of the avian cases which were studied were the lungs affected at all. The chief attack of bird tuberculosis falls upon the liver. It becomes enormously enlarged and crowded with nodules of various sizes. Tuberculosis of the bones and joints is much more common in birds than in mammals.

The question as to whether tuberculosis affects reptiles was not determined by the author's observations. One case in a tortoise seemed to be tuberculosis, but the germs did not respond completely to Koch's tests.

The observations which were made by the author seem to indicate that the main channel of infection is by way of the alimentary tract, and that from this source it spreads to the lungs in mammals far more than in birds, by reason of the apparently greater resistance of the lungs in birds than in mammals.

Contribution to the tuberculin problem, VIQUERAT (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 10, pp. 293, 294*).—The author has made chemical analyses of tuberculin and tubercle bacillus and finds that the latter consists of an outer layer composed of a salt of palmitic acid which is not easily soluble in water, and an inner portion composed of a salt of succinic acid, which is more easily soluble in water. It is concluded, therefore, that tuberculin is not a proteid, but a definite chemical body. Tuberculin was heated to a temperature of 150 to 200° without its undergoing any change, and it still had the same effect upon tuberculous animals as before heating. Succinic acid plays the chief part in tuberculosis. The tubercle bacillus does not produce a toxin, but operates rather in the way of producing a diathesis. "Tuberculin is nothing but an aqueous solution of an alkaline succinate."

Report of the biologist, J. NELSON (*New Jersey Stas. Rpt. 1898, pp. 229-242*).—An outbreak of abortion in the college herd was checked by systematic disinfection with a 2 per cent solution of creolin, used lukewarm.

In a series of experiments with tuberculin in the college herd, the author found reason to believe that cattle may be infected with tuberculosis for some length of time before they will give a reaction to the tuberculin test, and thus concludes it is necessary to give the test about once a year, or at least once in 2 years, in order to be certain that the disease does not exist in the herd.

Abortion, barrenness, and fertility in sheep, W. HEAPE (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 2, pp. 217-248*).—The Royal Agricultural Society in 1897 issued circulars asking for information upon the subject of abortion, barrenness, and fertility in the various flocks of sheep throughout Great Britain. Tolerably complete returns were received from these requests concerning 397 flocks, including in all 122,673 breeding ewes. Of these flocks 338 were of pure-bred stock and 59 were crossbred. Eighteen pure breeds of sheep are represented in the returns, but only 8 of them in sufficient numbers to furnish reliable statistics for the breed. The other pure breeds in the count are put together for purposes of comparison with the crossbreeds.

The percentage of abortion which was suffered by 300 sheep owners varied from 23.75 per cent to 0. The Dorset Horn and Lincoln breeds suffered most from abortion, the Southdowns occupying an intermediate position in this respect, while the other pure breeds suffered least.

With regard to the causes of abortion, the observations of the author, based largely upon the experience of different sheep breeders, are set forth under a number of different heads. The statistics collected indicate that shearling ewes are more liable to abort than older ones. Fright from strange dogs, shooting, or thunder, and overexertion from jumping ditches, etc., have been known to cause abortion.

With regard to the locality and subsoil, certain differences in the proportion of abortion were found which would seem to indicate that some soils and some localities are more favorable to abortion than others. The returns show clearly that heavy rainfall occurring during the latter stages of gestation are apt to cause abortion. The above-mentioned factors in the production of abortion are, however, subordinate to the food and general condition of the ewes. From the statistics which the author collected, it was not apparent that any particular feeding stuff which is usually given to sheep was distinctly favorable or unfavorable to abortion. It should be stated, however, that several kinds of fodder, when given in undue quantity or at inopportune times, may precipitate abortion.

The percentage of barrenness reported by 327 sheep raisers varied from 51.42 to 0, the average percentage in 96,520 ewes being 4.71 per cent. Barrenness reaches ordinarily about twice as high a percentage as abortion, and only 3 breeds upon which reports were made showed less than 5 per cent of barrenness. About 2 per cent of the barrenness may be put down to the account of constitutionally barren ewes. A percentage higher than this is to be considered as due to causes which may be prevented. According to the statistics which were collected, barrenness was not perceptibly dependent upon the age of the ewes. It was noticed that barrenness was more frequent when young rams were used than in the case of older ones. The number of ewes per ram varied in the different flocks from 40 to 60. From the collected statistics no definite rules could be formulated regarding the influence of the fatness of the ewes or rams in the determination of barrenness. The total loss from barrenness and abortion was not under 4 per cent for any breed and was usually over 6 per cent.

With regard to fertility, the proportion of lambs reported by 306 sheep raisers varied from 203.8 to 59.09 per cent. The percentage of lambs for

107,603 ewes was 120.4 per cent. The percentage of twins recorded by 237 sheep raisers varied from 85.58 to 2.4 per cent, the percentage for 68,536 being 30.02. It is of interest to note that the fertility was higher in all of the pure-bred than in the crossbred sheep.

With regard to the causes of fertility, a great many factors have been assumed and are believed to contribute to its increase or decrease, but the primary factor would seem to be a constitutional one. It is shown, for instance, from the statistical records that twins are more frequently born from ewes which were themselves twins than from ewes which were single, and the indications are that careful selection of races may increase the fertility to a considerable extent. The percentage of twins which are born in any flock depends upon the constitutional characteristics of the ewe and not upon the ram. The general view of the results obtained by the observations of the author and by the compilation of these statistics, obtained as above indicated, may, perhaps, best be seen in the following table:

Variations in size of flocks and in percentage of lambs, twins, abortion, and barrenness.

Breed.	Number of flocks.	Average size of flock.		Lambs.		Twins.		Abortion.		Barren.	
		Rams.	Ewes.	Highest	Lowest.	Highest.	Lowest.	Highest.	Lowest.	Highest.	Lowest.
				P. ct.	*P. ct*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*	*P. ct.*

Tenth annual report on the veterinary service in Hungary, F. HUTYRA (*Jahresbericht über das Veterinärwesen in Ungarn. Budapest: Agr. Dept., 1899, pp. 222*).—This report contains an account of the instruction given in the Royal Veterinary School in Budapest, and of the general veterinary service and veterinary sanitation of Hungary. In the second part of the report numerous observations are recorded concerning anthrax, rabies, glanders, foot-and-mouth disease, pneumonia, sheep pox, mange, hog cholera, and swine plague. A summary is given of the results obtained by a protective inoculation against anthrax, blackleg, and hog cholera. A brief statement is made of the veterinary police regulations.

Infectious lung diseases and the present status of the question of Psittacosis, LEICHTENSTERN (*Centbl. Allg. Gesundheitspfl., 18 (1899), No. 7–8, pp. 241–303*).—An extended discussion of the agency of parrots in transmitting various lung diseases to man. A bibliography is added.

Studies in pathology and clinical symptoms. Experimental researches, P. J. CADIOT (*Études de pathologie et de clinique. Recherches expérimentales. Paris: Asselin & Houzeau, 1899, pp. 618, figs. 65*).—This volume contains a large number of clinical and pathological observations upon various diseases affecting domestic animals. An illustrated account is given of tuberculosis in the horse, in the dog, and in the cat, with extensive bibliographies of the subject for each of these species. Avian tuberculosis also receives an extended discussion at the hands of the author, in the course of which he comes to the conclusion that the tuberculosis of birds and of mammals is due to one and the same organism. Especial attention is devoted to tuberculosis in parrots, and the author calls attention to the frequency of the disease in this species and its relationship to the spreading of human tuberculosis. An account is given of tuberculosis in the goat by Gilbert and Roger. These authors have also assisted in various other parts of the book. Besides tuberculosis, various other diseases are discussed, such as glanders, eczema, endocarditis, infectious pneumonia, etc.

Studies on the resorption of cells, E. METCHNIKOFF (*Ann. Inst. Pasteur, 13 (1899), No. 10, pp. 737–769, pls. 2*).—In this paper the author reports the results obtained by a study of the activity of phagocytes and their relationship to immunity. The general conclusions may be summarized as follows: The resorption of cells is chiefly the work of macrophages. Macrophages may not only seize upon dead cells, but also upon cells which are evidently alive. Red-blood corpuscles of the goose injected into the peritoneum of guinea pigs were entirely devoured by the macrophages. The immunizing substances are probably an excretion of the macrophages at the end of a period of intracellular digestion.

The different reaction of certain micro-organisms in a colored nutrient medium A. CESARIS-DEMEL (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 18–19, pp. 529–540, pls. 2*).—The author experimented with a number of pathogenic organisms, including that of anthrax, diphtheria, and chicken cholera. The results of these experiments may be briefly summarized as follows: The micro-organisms produce changes in the nutrient media by means of their biological products which furnish a convenient method for differentiating them. One of the most valuable media for this purpose was found to be liver broth stained with tincture of litmus.

The veterinary service in Bosnia and Herzegovina since 1879 (*Das Veterinärwesen in Bosnien und der Hercegovina seit 1879. Sarajevo, 1899, pp. 228, pls. 8*).—An account of the development of the veterinary service, with statistical reports on the extent of various infectious diseases and the preventive and curative methods adopted.

The origin of antitoxin: Is it present in the blood of some normal animals, L. COBBETT (*Lancet [London], 1899, No. 3962, pp. 332–337*).—Of 11 horses examined, 8 were found to possess diphtheria antitoxin in the blood.

On the significance of mixed infection in pulmonary tuberculosis, A. SATA (*Beitr. Path. Anat. u. Allg. Path., 1899, Sup. 3, pp. 179, pls. 2*).—The results of this study may be briefly summarized as follows: In man and animals mixed infection plays an important part in the pulmonary forms of tuberculosis. Mixed infection is usually subsequent to tubercular infection. Pulmonary tuberculosis is pure tuberculosis only in its earlier stages, the majority of advanced cases showing a mixed infection. The latter process is largely responsible for elevation of temperature and pneumonic conditions. The bacteria which are most frequently found in mixed infection are *Streptococcus pyogenes, Staphylococcus pyogenes aureus, Diplococcus pneumoniæ, Pneumobacillus,* and *Pseudodiphtheriabacillus.* Probably a mixed infection does not always hasten the progress of tuberculosis, but may in some cases check the development of the tubercle bacillus.

Concerning the preparation of tubercle bacilli, ROSSO (*Mod. Zooiatro, 10 (1899), No. 10, pp. 182, 183*).—A study on the biological technique of the bacillus of tuberculosis.

The demonstration of tubercle bacilli in the tubercles of beef, P. STAZZI (*Mod. Zooiatro, 10 (1899), No. 9, pp. 164–171, fig. 1*).—A discussion of the methods by which the bacillus is detected.

The frequency of bovine tuberculosis, M. STREBEL (*Schweiz. Arch. Thierh., 41 (1899), No. 6, pp. 264–267*).—A statistical account.

Tuberculosis in the horse, Körner (*Ztschr. Veterinärk., 11 (1899), No 12, pp. 621-624*).—Tuberculin did not give a typical reaction, although the disease was well established.

The importance of tuberculin for diagnostic purposes, Z. Blaustein (*Oesterr. Monatschr. Thierh., 24 (1899), No. 11, pp. 512-513*).

Report on an investigation with regard to the value of tuberculin as a test of the presence of tuberculosis in cattle, J. M. Young (*Veterinarian, 72 (1899), No. 863, pp. 787-790*).—Results obtained by this study are briefly summarized as follows: Tuberculin loses its virulency when kept for any considerable time. It is a reliable diagnostic agent except when the tubercular lesion is minute or where the disease has become generalized. Tuberculous udder is of more frequent occurrence than is usually supposed.

The application of the tuberculin test among cattle on a farm in southern Holland, J. F. Laméris (*Tijdschr. Veeartsenijk. en Veeteelt, 27 (1899), No. 1, pp. 5-16*).—Extensive tables are given showing the temperature reactions and qualities of milk produced during the experiment.

Combating tuberculosis, D. Rosenbusch (*Oesterr. Monatschr. Thierh., 24 (1899), No. 7, pp. 289-293*).—A discussion of the effects of the sanitary regulations of Bosnia and Herzegovina regarding tuberculosis.

The contest against bovine tuberculosis, G. Regner (*Meddel. K. Landtbr. Styr., 1899, No. 55, pp. 29*).

Serum therapy in the treatment of tuberculosis, E. Maragliano (*Berlin. Klin. Wohnschr., 36 (1899), No. 49, pp. 1073-1075*).—By experiments upon guinea pigs and rabbits, the author found that it was possible to obtain an antitoxin which will protect these animals against fatal doses of the tubercle toxin. Of the guinea pigs which were inoculated with tuberculosis and later treated with antitoxin, 50 per cent were cured.

The action of soluble products of Streptothrix on infections produced by Actinomyces farcinicus and on the course of experimental tuberculosis, Sabrazès et al. (*Compt. Rend. Soc. Biol., Paris, 11. ser., 1 (1899), No. 35, pp. 929-930*).—In rabbits the progress of tuberculosis was not retarded by inoculation with these products.

An attempt at treatment of tuberculosis by cultures of the Eberth and coli bacilli, A. Rodet (*Compt. Rend. Soc. Biol., Paris, 11. ser., 1 (1899), No. 34, pp. 907-908*).—Nine guinea pigs were inoculated with human tuberculosis of a low virulence. Three of these animals were kept for control. The other 6 were inoculated 12 days later, 3 with Eberth bacillus and 3 with coli bacillus. They received inoculations at intervals of a few days for a period of nearly 2 months. All the animals which were treated died after from 110 to 200 days, and *post-mortem* examinations showed that the treatment had not checked the progress of the disease in invading the various organs.

The use of serum against anthrax, J. Mendez (*Centbl. Bakt. u. Par., 1 Abt., 26 (1899), No. 20-21, pp. 599-608*).—A serum was produced which exhibited a specific action against anthrax in guinea pigs. Many cases of anthrax in man have been treated with serum in the Argentine Republic. Uniformly good results were obtained. After injection of the serum the temperature falls, the œdematous condition passes away, and the glands assume their normal size. Cattle and sheep were treated with serum for anthrax with excellent results.

The production of toxin by anthrax bacilli, H. Conradi (*Ztschr. Hyg. u. Infectionskrank., 21 (1899), No. 2, pp. 287-316*).—The author gives a review of the literature, with an extensive bibliography. The results of the work may be expressed as follows: Anthrax bacillus produces neither soluble, extracellular, nor intracellular toxin in either susceptible or nonsusceptible animals.

Diseases of cattle that may be mistaken for foot-and-mouth disease, B. Bang (*Maanedsskr. Dyrlæger, 11 (1899), No. 4, pp. 157-166*).

Foot-and-mouth disease, J. WOHLMUTH (*Oesterr. Monatschr. Thierh., 24 (1899), No. 5, pp. 225, 226*).—An account of an outbreak of this disease.

Combating foot-and-mouth disease, D. GAUTIER (*Maanedsskr. Dyrlæger, 11 (1899), No. 8, pp. 273–296*).—A report of the discussion of this disease held during the Seventh International Veterinary Congress.

The etiology of Texas fever, T. SMITH (*New York Med. Jour., 70 (1899), No. 2, pp. 47–51*).—A general discussion of the relationship of the tick to the micro-organism of the disease, with special reference to theories concerning the means of transmission of malaria.

Red water, or Texas fever, A. EDINGTON (*Lancet [London], 1899, No. 3949, pp. 1219, 1220*).—Reports a number of successful experiments in inoculating cattle with the blood of recovered animals.

Inoculation for Texas fever, J. W. CONNAWAY (*Breeders' Gaz., 36 (1899), No. 20, pp. 596, 597, figs. 4*).—A report on recent successful inoculations made at the Missouri Station against this disease.

Bovine tick fever (*Indian Agr., 24 (1899), No. 8, p. 252*).—A brief article on the disease as found in the southern English colonies.

Studies on pleuro-pneumonia, NOCARD ET AL. (*Rec. Méd. Vét., Paris, 8. ser., 6 (1899), No. 22, pp. 430–446*).—A report upon experiments in which the authors determined that serum inoculations may be depended upon both as a curative and preventive measure.

Contagious pleuro-pneumonia of cattle, R. GUISEPPE (*Mod. Zooiatro, 10 (1899), Nos. 19, pp. 372–375; 20, pp. 393–399; 21, pp. 414–418; 22, pp. 431–435*).—An experimental and critical study of the symptoms, treatment, prevention, prevalence, and geographical distribution of this disease.

Experimental production of acute fibrinous pneumonia by pneumococcic toxin, P. CARNOT (*Compt. Rend. Soc. Biol., Paris, 11. ser., 1 (1899), No. 35, pp. 927–929*).

The preventive properties of the blood serum of an immunized heifer as used against contagious pleuro-pneumonia, ARLOING and DUPREZ (*Jour. Méd. Vét. et Zootech., 5. ser., 3 (1899), pp. 641–645*).

Recent work in the production of immunity against blackleg, H. VALLÉE (*Rev. Vét. [Toulouse], 24 (1899), No. 12, pp. 726–737*).

Preventive inoculation against blackleg, T. KITT (*Monatsh. Prakt. Thierh., 11 (1899), No. 2, pp. 49–62*).—By inoculating horses, sheep, goats, and cattle with blackleg virus the author was able to obtain a serum which protected sheep against a fatal subcutaneous dose of fresh or dry blackleg material. The immunity thus produced persisted in the experimental animals for 2 months. Similar experiments were not tried on cattle, on account of the expense connected with buying such animals.

Malignant œdema in cattle, J. C. POUND (*Queensland Agr. Jour., 5 (1899), No. 5, pp. 505–508, figs. 2*).—A description of an outbreak of this disease, with an account of the *post-mortem* findings and of the growth of the pathogenic organism upon different culture media.

The rational treatment of milk fever of the septic form, G. GAMBAROTTA (*Mod. Zooiatro, 10 (1899), No. 10, pp. 191–196*).—Recommends strict antiseptic methods.

The anatomy of the udder and its diseases, L. B. BRANTE (*Nord. Mejeri Tidn., 14 (1899), No. 32, pp. 436–438*).

Poisoning of cows from moldy hay, O. STENSTRÖM (*Nord. Mejeri Tidn., 14 (1899), No. 27, pp. 368, 369*).

Poisoning of cattle by reed meadow grass (Glyceria aquatica), E. SCHOUG (*Landtmannen, 10 (1899), No. 28, pp. 455–457*).

Some poisonous plants, G. B. PLOTTI (*Clin. Vet., 22 (1899), No. 43, pp. 507–509*).—Several cows were poisoned by eating *Æthusa minor* and *Conium maculatum*. Rubbing the body with camphorated oil, giving clysters of ammonia and alcoholic stimulants by way of mouth were only partially effective.

The etiology of omphalitis in calves, A. WILHELMI (*Landw. Jahrb. Schweiz, 13 (1899), pp. 121-134, pl. 1*).—In the study of this disease 15 different organisms were investigated. *Bacterium coli commune* and *B. septicæmiæ hæmorrhagicæ* were the only ones which produced pathogenic effects in inoculation experiments. The author gives tables of temperatures and the *post-mortem* findings in a number of calves which died of the disease. *Bacterium coli commune* is considered to be the pathogenic organism of omphalitis. The disease arises from a local infection by this organism.

Endoglobular hæmatozoa of sheep, LAVERAN and NICOLLE (*Compt. Rend. Soc. Biol., 11. ser., 1 (1899), No. 30, pp. 800-802*).—An epizootic of sheep near Constantinople was studied by the authors. It was found that the blood, and especially the spleen, contained large numbers of a parasitic organism. The disease seemed to be the same as that known in Roumania by the name of carceag. The authors believe that the hæmatozoon which they found in the blood is closely related to the organism of Texas fever, and should be placed in the same genus as the latter, and known therefore by the name *Piroplasma (Pyrosoma) ovis*.

Liver fluke in the spleen of sheep, S. VON RATZ (*Centbl. Bakt. u. Par., 1 Abt., 26 (1899), No. 20-21, pp. 616-618*).—Notes on *Distomum hepaticum* found in this situation.

A new pathogenic Streptothrix, SILBERSCHMIDT (*Ann. Inst. Pasteur, 13 (1899), No. 11, pp. 841-853, figs. 5*).—*Streptothrix capræ* was found to be the cause of a disease of goats which closely resembles tuberculosis. The organism was grown on various nutrient media. Inoculation experiments were conducted upon rabbits, guinea pigs, and white mice. In the rabbit, subcutaneous injections produced tubercles in various organs, and the structure of the tubercles was similar to that of tubercles caused by Koch's bacillus. White mice withstood the action of the organism, although an abscess was formed at the point of inoculation. Guinea pigs were affected in nearly the same manner as rabbits.

Etiological studies on swine plague and swine septicæmia, H. PREISZ (*Ztschr. Tiermed., 2 (1898), No. 1, pp. 1-66*).—An extensive experimental investigation of the cause of swine plague. The author devoted especial attention to the effects of mixed infection in this disease, and upon the production of immunity. A bibliography is added to the article.

The resisting power of the organism of hog cholera, J. KARLINSKI (*Oesterr. Monatschr. Thierh., 24 (1899), No. 3, pp. 122-130*).—A study of the effect of heat and chemical antiseptics upon the organism of hog cholera.

Swine plague, T. KASPAREK (*Oesterr. Monatschr. Thierh., 24 (1899), No. 11, pp. 481-492: 12, pp. 529-537*).—An experimental study of the bacteriology, symptoms, and treatment of swine plague. An extensive bibliography is appended to the article.

Protective inoculation against hog cholera, MARKS (*Berlin. Tierärztl. Wchnschr., 1899, No. 46, pp. 553, 554*).—Out of 14,320 animals inoculated, 54 died as a result of the inoculation.

Eradication of hog cholera in Austria (*Oesterr. Monatschr. Thierh., 24 (1899), No. 8, pp. 365-369*).

Feeding experiments with American pork, J. BÖHM (*Ztschr. Fleisch u. Milchhyg., 10 (1899), No. 3, pp. 41, 42*).—Pork infested with trichinæ was fed to rats to determine the question whether the trichinæ had been killed by the salt. The rats did not become infested.

Chronic cough of young pigs, TEETZ (*Berlin. Tierärztl. Wchnschr., 1899, No. 47, pp. 566-567*).—The mortality from this disease usually reaches from 40 to 60 per cent. The symptoms of the disease are described by the author. The lungs are affected and show a hepatization, but the affection is not related to swine plague.

The use of Hayem serum in puerperal septicæmia of swine, C. FABRETTI (*Mod. Zooiatro, 10 (1899), No. 22, pp. 426-428*).

Airol, W. EBER (*Ztschr. Tiermed., 2 (1898), No. 3, pp. 161-168*).—The antiseptic power of this substance is about the same as that of iodoform. Experimental studies are reported in regard to its effects on a number of bacteria.

AGRICULTURAL ENGINEERING.

Water-right problems of Bear River, C. T. Johnston and J. A. Breckons (*U. S. Dept. Agr., Office of Experiment Stations Bul. 70, pp. 40, pls. 9*).—This bulletin discusses the subject of interstate water rights as illustrated in the Bear River Valley, and is the third of a proposed series of bulletins of "information regarding the actual status of irrigation in the arid region." Previous bulletins of the series are Bulletins 58 and 60 of this Office (E. S. R., 11, pp. 95, 96). The Bear River "was chosen for study because in its course of a little over 300 miles it crosses State lines (Wyoming, Idaho, and Utah) five times, finally emptying into Salt Lake, which is less than 50 miles distant from its source, thus presenting in small compass a great variety of interstate problems, and offering exceptional opportunities for the inauguration of this class of inquiries."

Water-supply engineering, A. P. Folwell (*New York: John Wiley & Sons, 1900, pp. XIV+562, ill.*).—This book treats of "the designing, construction, and maintenance of water-supply systems, both city and irrigation."

Hartz River Valley irrigation scheme; reports of H. C. Litchfield, engineer in charge, to the chief inspector of public works, Cape of Good Hope, and covering letters by the chief inspector (*Capetown: W. A. Richards & Sons, 1899, pp. 53, map 1*).

Irrigation by artesian water (*Queensland Agr. Jour., 5 (1899), No. 5, pp. 459, 460*).—A brief account of such irrigation in Queensland.

Reservoir survey, F. H. Newell (*Irrig. Age, 14 (1899), No. 3, pp. 79–82*).—An explanation of the relation of the United States Geological Survey to this work.

Duty of water—general instructions to observers, E. Mead (*U. S. Dept. Agr., Office of Experiment Stations, Irrig. Invest. Schedule 2, pp. 4, figs. 2*).—This circular gives general instructions for the measurement of water used in irrigation, including directions for the construction of a Cippoletti weir and a measuring flume, and a table showing the discharge over weirs of various dimensions.

The prevention of water-right litigation, S. Fortier (*Irrig. Age, 14 (1899), No. 3, pp. 83–89*).—The main features of the system proposed and upon which it is claimed the majority of western people are agreed are as follows:

"(1) The creation in each State of a central bureau of irrigation to which all data pertaining to this subject should be forwarded and from which information could be obtained.

"(2) The appointment of competent parties to collect and collate the physical facts pertaining to the irrigable lands and the appropriated waters with a view to the final settlement of all water rights.

"(3) The establishment of a special tribunal to grant water titles for a nominal sum on the basis of carefully determined facts rather than on the conflicting evidence of a large number of volunteer witnesses.

"(4) The organization of an efficient administrative system to divide equitably the utilized waters of the State."

Form for weekly record of use of irrigation water (*U. S. Dept. Agr., Office of Experiment Stations, Irrig. Invest. Schedule 1*).

Kinematics of machinery, J. H. Barr (*New York: John Wiley & Sons, 1899, pp. V+247, figs. 213*).—"This little book is intended as a text-book for use in the general course in mechanical engineering schools, or for use by draftsmen and others who may desire to study the methods of graphical analysis of machine motions."

Report on highways in Maryland (*Rpt. Maryland Geol. Survey, 3 (1899), pp. 461 + 80, pls. 35, figs. 38*).—This includes articles on The highway investigations by the Maryland Geological Survey and The relations of Maryland topography, climate, and geology to highway construction, by W. B. Clark; Highway legislation in Maryland and its influence on the economic development of the State, by G. L. Sioussat; The present condition of Maryland highways and Construction and repair of roads, by A. N. Johnson; Qualities of good road metals and the methods of testing them, The administration of roads, including the method and expense of road improvements, and The advantages of good roads, by H. F. Reid. The laws of Maryland relating to highways are given in an appendix.

STATISTICS—MISCELLANEOUS.

Twenty-second Annual Report of Connecticut State Station, 1898 (*Connecticut State Sta. Rpt. 1898, pp. 341 + XIV*).—This is made up of a number of articles abstracted elsewhere and a brief general report including the organization list of the station, various announcements, an outline of station work by the board of control, and a report of the treasurer for the year ended September 30, 1898.

Annual Report of New Jersey Stations (*New Jersey Stas. Rpt. 1898, pp. XIX + 467, pls. 30, figs. 5, maps 2, dgms. 2*).—This includes a financial statement of the State station for the year ended October 31, 1898, and of the college station for the fiscal year ended June 30, 1898; a report of the director reviewing the work of the different departments; reports of the chemists, assistant in horticulture, assistant in dairy husbandry, biologist, botanist, and entomologist, abstracted elsewhere; and a reprint of Bulletin 133 of the station on peach growing (E. S. R., 11, p. 51).

Report of the Department of Agriculture of Norway for 1898 (*Aarsber. Offent. Foranst. Landbr. Fremme, 1899, pp. LXXIX + 487*).

The needs of Agriculture (in Russia) and the measures required for meeting them (*St. Petersburg: Min. Agr. and Imp. Domains, 1899, pp. 316; rev. in Selsk. Khoz. i Lyesov., 192 (1899), Mar., pp. 707, 708*).—The first and greatest need is said to be the necessity of a broad diffusion of general education and agricultural information as well as of special agricultural education. Among the other most essential measures recommended are a decrease of the import duties, diminution of various taxes, a broad organization of government credit, a change of the railway transportation charges, etc.—P. FIREMAN.

University extension in agriculture, A. C. TRUE (*Forum, 1900, Feb., pp. 701–707*).

Fourth report of committee on methods of teaching agriculture (*U. S. Dept. Agr., Office of Experiment Stations Circ. 41, pp. 7*).—A syllabus for a course of instruction in zootechny submitted as a report of progress to the convention of the Association of American Agricultural Colleges and Experiment Stations, held at San Francisco, Cal., July 5–7, 1899. Zootechny as a division of technical agriculture is limited by the committee to the theory and practice of the production of normal animals useful to man. The general topics in the outline are as follows: (1) Principles governing the choice and breeding of animals; (2) types and breeds of different kinds of animals; (3) principles of feeding; (4) practice of feeding different kinds of animals; (5) principles of hygiene and management, and (6) practice in the management of different kinds of animals.

A German common school with a garden, C. B. SMITH (*U. S. Dept. Agr., Office of Experiment Stations Circ. 42, pp. 7, figs. 2*).—The greater number of common schools in the smaller villages of Germany are described as having attached to them a small garden intended primarily for the use of the teacher. The ways in which this garden is occasionally made a means of instruction are pointed out, and one of the better schools of this kind, located at Alfter, in the German Rhine Province, is described in full. Instruction in fruit culture, gardening, and general farming is given 2 hours each week during the last 2 years of the course. Outline suggestions for this work as furnished by the provincial government are included in the circular.

NOTES.

Idaho University and Station.—A very successful farmers' short course of 10 days has been held at the university, which was an innovation in the State. The course was attended by 32 farmers and orchardists, who manifested the keenest interest in all the instruction imparted. Just previous to this short course the station conducted a farmers' institute at the university, which was largely attended.

Purdue University.—President J. H. Smart died February 21, 1900. Dr. Smart was for 27 years a member of the Indiana State board of education, served 3 terms as State superintendent of public instruction, and had been president of Purdue University since 1883.

Maine Station.—G. M. Gowell, formerly agriculturist, has been placed in charge of the department of stock breeding and poultry, and L. J. Shepard has become assistant agriculturist instead of assistant horticulturist.

Michigan Station.—T. T. Lyon, for the past 10 years in charge of the Michigan Fruit Substation at South Haven, died February 6, at the age of 87 years. Mr. Lyon has been actively interested in American horticulture for 60 years, and for many years has taken a prominent part in the work of the pomological society of his State and of the American Pomological Society.

Missouri Station.—J. G. Babb has been appointed secretary of the station in connection with his regular duties as secretary of the board of curators of the University, and Irvin Switzler, former secretary of the station, has been transferred to other university work.

Nevada University and Station.—P. B. Kennedy, of the Division of Agrostology of this Department, has been appointed associate professor of botany and horticulture in the university and station, and will enter upon his duties about July 1.

Oklahoma Station.—W. E. Bolton, secretary of the Oklahoma Live Stock Association, Woodward, Okla., has been appointed a member of the board of regents, vice J. D. Ballard, resigned.

South Carolina Station.—Incubator and brooder rooms have been added to the equipment of the poultry division.

Tennessee Station.—At a recent meeting of the board of trustees money was appropriated to erect a dairy building. This building will be 40 by 80 ft., of brick, 2 stories in height, with slate roof, and cement floor in the basement. It will have about 7,000 ft. of floor space, and the most complete machinery for dairy instruction will be installed. It will be used for instruction in commercial dairying, farm dairying, the manufacture of butter and cheese, and milk testing, and also for the experimental work in dairying.

Texas College and Station.—According to a recent decision of the State court of appeals (supreme court), the tenure of office of the trustees of public schools, regents of the State University, and directors of the Agricultural and Mechanical College is restricted to 2 years, because of constitutional limitation.

Necrology.—Prof. Carl Lintner, formerly director of the Bavarian Agricultural Central School, died at Munich January 14, 1900, at the age of 72 years, after a long illness. Professor Lintner had for many years devoted much attention to the science and practice of brewing and became the first authority on that subject. He inaugurated a very successful course in brewing at the agricultural school, which long since grew into an independent department, and in 1874, in company with Dr. Reischauer, he established at Munich the first experimental station for brewing, which was later adopted by an association of brewers.

O

EXPERIMENT STATION RECORD.

VOL. XI. NO. 9.

The statistics of the educational institutions receiving the benefits of the acts of Congress of July 1, 1862, and August 30, 1890, recently collated by this Office for the year 1899, show no change in the number of these institutions. In the United States, exclusive of Alaska, Hawaii, Porto Rico, and the Philippines, there are 64 such institutions, of which 61 maintain courses in agriculture.

The aggregate value of the permanent funds and equipment of the land-grant colleges and universities in 1899 is estimated to be as follows: Land-grant fund of 1862, $10,262,944; other land-grant funds, $1,441,577.38; other permanent funds, $14,442,194.25; land grant of 1862, still unsold, $4,062,850.30; farms and grounds owned by the institutions, $5,543,108.91; buildings, $16,009,274.53; apparatus, $1,955,859.21; machinery, $1,373,696.75; libraries, $1,854,942.21; miscellaneous equipment, $1,997,690.07; total, $58,944,137.61. The income of these institutions in 1899, exclusive of the funds received from the United States for agricultural experiment stations, was as follows: Interest on land grant of 1862, $624,672.88; interest on other funds, $651,864.85; United States appropriation under act of 1890, $1,120,778.96; State appropriation (annual or regular), $1,679,536.99; State appropriation (occasional), $608,380.99; tuition fees, $580,946.45; incidental fees, $177,343.91; miscellaneous, $550,512.58; total, $5,994,037.61. The value of the additions to the permanent endowment and equipment of these institutions in 1899 is estimated as follows: Permanent endowment, $1,411,325.29; buildings, $452,033.19; library, $117,693.99; apparatus, $120,901.23; machinery, $115,336.20; miscellaneous, $147,862.53; total, $2,365,152.43. The number of persons in the faculties of the colleges of agriculture and mechanic arts were as follows: For preparatory classes, 315; for collegiate and special classes, 1,669; total, 1,878. In the other departments the faculties aggregated 1,015, making a grand total of 2,893 persons in the faculties of the land-grant institutions. The students in 1899 were as follows: (1) By classes—preparatory, 6,658; freshmen, 7,093; sophomores, 4,500; juniors, 3,715; seniors, 2,846; special, 10,399; post graduate, 745; total, 35,956. (2) By courses—agriculture, 4,407; mechanical engineering, 3,355; civil engineering, 1,463; electrical engineering, 1,325; mining engineering, 713; architecture, 410; household economy, 1,573; veterinary science, 646; military tactics, 10,416. The graduates in 1899 were 2,232, and since the organization of these institutions 39,084. The average age of graduates in 1899 was 22 years 2 months. The total number of volumes in the libraries was 1,463,845. The total number of acres of land granted to the State under the act of 1862 was 9,359,241, of which 985,833 are still unsold.

Agricultural experiment stations are now in operation under the act of Congress of March 2, 1887, in all the States and Territories. Agricultural experiments have been begun in Alaska with the aid of national funds, and an experiment station is in operation in Hawaii under private auspices. In each of the States of Alabama, Connecticut, New Jersey, and New York a separate station is maintained wholly or in part by State funds, and in Louisiana a station for sugar experiments is maintained partly by funds contributed by sugar planters. Excluding the branch stations established in the several States, the total number of stations in the United States is 54. Of these 52 received the appropriation provided for in the act of Congress above mentioned. The total income of the stations during 1899 was $1,143,334.93, of which $720,000 was received from the National Government, the remainder, $423,334.93, coming from the following sources: State governments, $240,300.20; individuals and communities, $12,100; fees for analyses of fertilizers, $75,294.42; sales of farm products, $69,312.60; miscellaneous, $26,327.71. In addition to this the Office of Experiment Stations had an appropriation of $40,000 for the past fiscal year, including $10,000 for the Alaskan investigation. The value of additions to equipment of the stations in 1899 is estimated as follows: Buildings, $27,218.64; libraries, $10,796.15; apparatus, $16,917.07; farm implements, $10,784.88; live stock, $16,265.95; miscellaneous, $22,521.93; total, $104,504.62.

The stations employ 678 persons in the work of administration and inquiry. The number of officers engaged in the different lines of work is as follows: Directors, 71; chemists, 148; agriculturists, 68; experts in animal husbandry, 9; horticulturists, 77; farm foremen, 21; dairymen, 23; botanists, 52; entomologists, 48; veterinarians, 26; meteorologists, 17; biologists, 7; physicists, 7; geologists, 5; mycologists and bacteriologists, 20; irrigation engineers, 5; in charge of substations, 16; secretaries and treasurers, 24; librarians, 9, and clerks, 43. There are also 48 persons classified under the head of "miscellaneous," including superintendents of gardens, grounds, and buildings, apiarists, herdsmen, etc. Three hundred and eight station officers do more or less teaching in the colleges with which the stations are connected.

During 1899 the stations published 445 annual reports and bulletins, containing 16,924 pages. Besides regular reports and bulletins, a number of the stations issued press bulletins, which were widely reproduced in the agricultural and county papers. The mailing lists of the stations aggregate 523,970 addresses.

In his report on the work and expenditures of the stations for the year ended June 30, 1899, the Director of this Office makes the following general statements:

The work of the stations during the past year has for the most part been along the same lines as heretofore, and in the aggregate a large amount of useful work has been accomplished. By their own efforts and with the aid of the colleges of agriculture and the State boards or commissioners of agriculture the stations are bringing their work home more closely to the farmers through publications, farmers' institutes, agricultural associations, home reading courses, and the press. It is becoming evident that farm practice in this country is being materially affected by the work of the stations, and they are more and more relied upon by our progressive farmers for advice and assistance.

The wisdom of Congress in making the Hatch fund a research fund is every year becoming more apparent. This Department is therefore disposed to more strongly insist on a strict interpretation of this act in this direction, and to hold that it is not only in accordance with the obligation, but also to the interest of the States, to devote the Hatch fund to investigations in agriculture and to supplement this fund as far as may be necessary to promote the interests of agriculture in other lines.

The movement for the improvement of courses of agriculture in the colleges with which the stations are connected is steadily growing. The past year has witnessed many changes for the better as regards specialization of the work of instruction and the development of courses suited to the varied needs of students. More than ever before the colleges are reaching out beyond their class rooms and are carrying useful instruction to the farmers through farmers' institutes, correspondence courses, and other forms of so-called university extension. As this outside work becomes better organized it is more apparent that it belongs to the college rather than the station.

As the work of both college and station grows in extent and complexity, it becomes more apparent that in order to perform the most efficient service the station should be organized strictly as a separate department of the institution with which it is connected, and that it should have an organization so compact that its work may proceed in accordance with a schedule carefully planned and energetically administered. To secure this end, experience shows that it is quite desirable that the station should have a competent executive officer, who can devote his time very largely to planning and directing its operations, managing its general business, and representing its interests before the public. It is encouraging to observe that in several States during the past year these considerations have led to the more complete separation of the business of the station from the general business of the college, and to the appointment of a director of the station as a separate officer.

From the very first the stations in this country have been largely engaged in the inspection of commercial fertilizers, and this work has been so efficiently and usefully conducted that from time to time additional inspection duties have been laid upon the stations. The movement for the establishment of different kinds of inspection service under authority of the National and State governments is growing apace, and it is very important that the relations of this work to the other functions of the stations should be clearly understood. Soon after the establishment of the stations under the Hatch Act this Department ruled that the funds appropriated under this act could not be legitimately applied to pay the expenses of the inspection and control of fertilizers. The same principle holds good with reference to other forms of inspection service demanded of the stations. While the methods and usefulness of inspection in any particular line are still problematical it may be justifiable for a station to take up this work to a limited extent, but as soon as it becomes a matter of routine business the State should provide funds for its maintenance. If it seems expedient that any part of the inspection service should be performed by the station under State laws and at State expense, the matter should be so arranged as not in any way to interfere with the investigations of the station. It is a great mistake to divert the time and energy of a competent investigator to the toilsome routine work of inspection service.

The number and importance of the experiments which the stations are conducting in cooperation with practical farmers and horticulturists have greatly increased of late. Thousands of such experiments are now annually conducted in the United States. These range all the way from simple tests of varieties of plants to special experiments in the management of farm or horticultural crops, live stock, or particular operations, such as tobacco curing. It is coming to be more clearly recognized that the field operations in agriculture or horticulture conducted on the station farm need to be supplemented by similar work in a considerable number of localities in order to be of general usefulness to the State. By going into different localities, as the needs of its work demand, the station can make itself more useful to the State as a whole. Without doubt cooperative experiments need to be very carefully planned and thoroughly supervised to be successfully conducted, and their success depends on their quality rather than their number. It is encouraging to observe that more careful attention is being given to this important matter by station officers, and it is believed that this work may be made much more economical and useful than the permanent substations as ordinarily managed.

ADAPTATION OF METHODS OF CULTIVATION AND MANURING TO THE PHYSICAL PROPERTIES OF SOILS.

EWALD WOLLNY, PH. D.,

Professor in the Technical High School at Munich.

In a previous article (E. S. R., 11, p. 604) various questions suggested by the relations of the physical properties of soils to the growth of plants were considered, from the standpoint of the soil. It is evident from the facts there pointed out, however, that it is necessary to also consider the subject from the standpoint of the plant in order that those methods of culture may be adopted which will prove most effective under given conditions of soil and systems of manuring. It is this phase of the subject which is discussed in the following pages.

Plants vary widely in their requirements as regards temperature, moisture, and texture of the soil, and these differences must be taken into consideration in the selection of crops to be cultivated. Detailed scientific investigation is needed, however, on this point, for our knowledge of this phase of the subject is almost entirely based on experience.

The rotation of plants which should be adopted is an important question, which can not be answered on chemical or purely agricultural grounds. To answer this question satisfactorily, the texture of the soil and its relation to water must be known. Plants requiring large amounts of water should, as a rule, precede those which do not require much water, or those which are not to be planted for several months after the first crop, during which time the soil lies fallow and has an opportunity to become thoroughly wet. In case of those plants which furnish little shade to the soil, or which have long periods of growth (perennial forage plants), the soil becomes hard, and should be allowed to lie fallow in order to acquire the mechanical condition necessary for other crops. The compacting of the soil during the cultivation of perennial forage plants is a matter of great practical importance, because it results in case of fine-grained soils in so limiting the quantity of air that normal decomposition of organic matter[1] is interfered with, processes of deoxidation are set up, and the fertility of the soil diminished. For these reasons crops having long periods of growth should be avoided as much as possible on soils of this kind. The injurious effect of lack of cultivation is most strikingly illustrated in meadows in which the deficiency of air results in an abnormal decomposition of the remains of the plant roots forming large accumulations of humus or turf. As ordinary means (direct removal of water, treatment with lime, and manuring) are, as experience has shown, insufficient to satisfactorily correct the unfavorable condition in question, it would seem that we ought to abandon the traditional system of meadow cultivation and replace it by one better adapted to natural requirements. The greatest advantages are unquestionably offered by that system which replaces meadow culture by field culture for a short time. In the case of these so-called "rotation meadows" (*Wechsel-wiesen*) the soil, as soon as it begins to show injury from the continuous growth of forage plants, is quickly restored to a favorable condition by plowing and by cultivation in hoed crops, which require frequent stirring of the soil.

---

[1] E. Wollny: Die Zersetzung der organischen Stoffe und die Humusbildungen in Rücksicht auf die Bodencultur. Heidelberg: Carl Winter, 1897 (E. S. R., 8, p. 879).

In the case of mixed culture, *i. e.*, where two or more crops are raised at the same time on the same field, the condition of both temperature and moisture must be taken into consideration. On soils of low water capacity and great permeability and in which the water content varies widely with the precipitation, the best results will be obtained by growing a mixture of crops with variable water requirements. This is true both for grain and for forage plants. Under such conditions mixed culture is much more reliable than the cultivation of a single crop. In the warmer climates, where the temperature of the soil often rises to a point dangerous to many plants, mixed culture may be practiced to advantage as follows: Plants that require heat and that grow to considerable height (fruit trees, vines on trellises, mulberry trees, etc.) are planted in rows, and the shaded strips of land lying between the rows are devoted to plants, such as the various cereals, which require considerable amounts of moisture and comparatively low temperatures. In warm climates with an insufficient supply of moisture special provision must be made for conserving the soil moisture in the case of such plants as hops, vines, etc. Under such conditions these plants should be trained so as to shade the ground as much as possible, and thus to reduce evaporation.

The relation of the physical properties of the soil to the planting and germination of seed[1] remain to be considered. Among the factors of prime importance in this connection is temperature. As is well known, germination begins at a certain minimum temperature, which varies widely with different plants and different varieties. Activity of germination increases with temperature up to a certain limit (optimum), but declines after this limit is passed, until it entirely ceases at a certain maximum temperature. In the colder climates, in which the temperature at seed time rarely rises above the optimum limit, it is necessary to pay close attention to the minimum temperatures of germination, especially in the spring. The seed must not be planted before the soil has reached the minimum temperature required by each plant, otherwise the seed lies in the soil without germinating and is likely to be destroyed. Such care is not necessary in the autumn, because unless the time of planting is very much delayed the soil is still comparatively warm, germination proceeds rapidly, and the dangerous period of early growth is easily passed. In the warmer climates, as well as in colder climates during the summer, the temperature may pass beyond the maximum limit for certain plants and serious injury result.

---

[1] E. Wollny: Saat und Pflege der landwirthschaftlichen Culturpflanzen. Berlin: Paul Parey, 1885. Die Cultur der Getreidearten. Heidelberg: Carl Winter, 1887.

Another factor of equal importance with temperature in determining the time of planting is the moisture of the soil. In case of soils which have a low water capacity and readily dry out in the upper layers, planting must be done while the soil is still moist; that is, as early in spring as the temperature will permit. On the other hand, planting should not be done when soil is too wet, since in wet soils the supply of oxygen is insufficient for germination. Soils should be cultivated only when they have dried out sufficiently so that the air can enter without hindrance.

The rate of seeding must be determined largely by the physical properties of the soil, since the amount of water at the disposal of the plant is, as already shown, so largely dependent upon these properties. The larger the available supply of water in the soil the closer the seed may be planted. The disadvantages of close planting become more evident as the storage capacity of the soil for water diminishes. They are most marked in case of sandy soils and others of loose structure resting upon a permeable subsoil. In such cases the water supply is comparatively limited, and close planting would be a serious mistake. Even under most favorable conditions the yield would be reduced, while under unfavorable conditions—for example, during a long drought—the plants would die for lack of moisture. Under certain conditions close planting may be desirable in case of soils of high water capacity, in order that the increased transpiration from the plants may remove the excess of water from the soil. A further reason for the use of more seed on soils of close texture than on those of loose texture is the fact that in the former the conditions are not favorable to complete germination or to extensive growth of roots.

In determining the proper depth of planting, the principal factors to be considered are aeration, moisture supply, and texture of the soil. In light, loose soils, which dry out readily, seed should be planted deeper than in close, heavy soils, which dry out slowly. There is no danger in deep planting on the lighter soils, because their porosity is such that air readily penetrates them to considerable depths. Light covering of the seed in case of heavy, fine-grained soils is advisable, because such soils have little permeability for air and their particles cohere so strongly that a crust is likely to be formed that offers great resistance to the growth of the young plantlets.

The physical properties of soils furnish a guide in the use of manures.

Considering first the most important fertilizer, barnyard manure, several important rules based upon the properties of soils in their relation to the decomposition of organic matter and the assimilation of plant food may be laid down. These rules are as follows: In clayey, fine-grained soils, in which decomposition proceeds slowly and percolation of water is inconsiderable, stable manure is most effective when worked into the soil in a condition of advanced decomposition. In these soils, however, in which organic matter decomposes rapidly and percolation is copious, it is better to use stable manure in a condition of less advanced decomposition, in order to prevent a possible loss of its fertilizing constituents by leaching. The objection frequently made to this procedure, that the soil does not contain the moisture necessary for decomposing coarse manure, does not hold if the manure is not covered too deep and if proper precautions are taken to reduce evaporation.

The physical properties of the soil must also be taken into account in determining the rate, time, and depth of application of manure which will give the best results. Large applications of manure on light, sandy soils may result in a loss of much of the fertilizing constituents of the manure by leaching, because such soils have little power of absorbing and retaining the soluble fertilizing constituents which are rapidly formed under these conditions. In view of these facts, it seems advisable that (1) sandy soils should not be heavily manured at any one time, but should receive frequent small applications; (2) the manure should be applied to the soil only a short time before the seed is planted and should be plowed in, and (3) it should be applied at a greater depth than in heavy soils. These rules should be observed more carefully the farther the decomposition of the manure has already advanced. In clayey, fine-grained soil, in which organic matter decomposes slowly, percolation is comparatively small, and the absorptive power of the soil for fertilizing constituents considerable, the manure should be used in larger quantities and less frequently, and it should be worked into the soil a longer time before cultivation. Furthermore, it should not be applied at a great depth (about 3 to 5 inches) below the surface, because only under such conditions can decomposition proceed properly in such soils. If manure is applied at greater depths in such soils, abnormal decomposition (putrefaction), due to lack of air, takes place, resulting in the formation of peat-like substances in the soil, which resist further decomposition for years.

The principal factors to be considered in the use of commercial fertilizers are water capacity, permeability of the soil, and percolation. With a limited supply of moisture in the soil, applications of materials containing readily soluble salts exert a harmful influence, both on germination and on the later growth of plants. If the precipitation is excessive and infrequent, a considerable proportion of the fertilizing constituents may be lost in soils of low-water capacity, the loss being greater the less the absorptive power of the soil. In such cases commercial fertilizers containing soluble salts should be applied in smaller quantities, but rather more frequently than on close compact soils or those which contain considerable amounts of humus. It might be advisable in case of sandy soils to use less soluble fertilizers, which are gradually transformed into a condition in which they are capable of assimilation. This is true especially of phosphoric acid, which is best applied on such soils in the form of bone dust or Thomas slag. The greatest care must be exercised in the use of fertilizers containing nitrogen in the form of nitric acid or ammonium salts (nitrate of soda, ammonium sulphate), since the soils have little absorptive power for these substances and they are readily removed by percolation. Such fertilizers should be applied only a short time before planting. With fine-grained, clayey soils and others which easily puddle and form a crust, care must be exercised to preserve a loose, crumbly condition of the surface soil, so that the supply of air may be sufficient to prevent decomposition of the nitrates and the escape of the nitrogen in the free state. As regards the danger of loss of fertilizing constituents, especially nitrates, by leaching, it should be remembered that percolation is likely to be greatest in a bare soil at the same time that the formation of nitrates is most active, *i. e.*, during the warmer portion of the year. The extent to which fertilizing constituents are lost by leaching of bare soils depends upon (1) the length of time the soil lies fallow, (2) the physical and chemical properties of the soil, and (3) the temporary conditions in the particular soil.

When, as in case of black fallow, the land lies bare for about a year a considerable quantity of the more readily soluble fertilizing constituents found in the soil, principally nitrates, are lost in the drainage waters, the amount of such loss varying with the precipitation and with the permeability of the soil. During the short periods between the growth of different crops, in which the soil must necessarily lie fallow on every farm, the extent of the loss depends upon the condition of the soil at the harvest of one crop and the length of time before the succeeding crop is planted. If a soil is allowed to lie fallow after a crop which has thoroughly used up its moisture or after a period of drought, loss of nitrates or other soluble constituents need not be feared, even if the planting of another crop is delayed until autumn. If, however, the soil contains considerable moisture at the time of harvesting a crop, and the land lies fallow over winter, some loss is unavoidable, especially if the season is wet and the soil permeable. In soils of the latter character, which often possess small absorptive power (sandy soils), the loss by leaching may include not only nitrates, but also the mineral constituents of the soil. In fine-grained soils, and those rich in humus, the losses resulting from lying fallow are not so large as in case of light soils, because of their greater absorptive power and less permeability. However, the loss, especially of nitrates, may be considerable even in these soils. The larger part of the nitrates formed during the summer remain in the soil until winter, provided the nitrates have been formed almost exclusively in the upper layers of the soil and have remained there. Crops planted in the spring following a dry winter find a large supply of nitrates in the soil. If, however, the summer during which the field has lain fallow is followed by a wet autumn and winter, the nitrates produced are largely lost by leaching.

For the purpose of preventing or reducing the losses, especially of nitrates, under such conditions, it seems to be advisable to plant catch crops, which are plowed under in the autumn, instead of allowing the land to lie fallow. By this means the nitrates stored up in the soil are transformed into organic compounds which during the succeeding winter are gradually rendered available. At the same time the growth of the catch crops tends to check percolation and reduce nitrification by diminishing the supply of moisture in the soil and increasing the temperature. For this purpose leguminous plants are especially valuable if there is sufficient time for their growth, because they increase the supply of nitrogenous matter in the soil. For short periods, a quick-growing plant, such as white mustard, should be selected.

The growth of catch crops is especially necessary when the fallow extends over a whole year, or from summer to the following spring, the climate wet, and the soil permeable and thoroughly wet at the beginning. When, however, the water of the soil has been exhausted by the preceding crop, and the fallow is to continue only until the following autumn, the methods outlined seem not only superfluous but may even be harmful, because in this case the principal object of fallowing, *i. e.*, collection of moisture in the soil, is not attained.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

A new method of determining nitrates, C. M. VAN DEVENTER (*Ztschr. Physikal. Chem., 31 (1899), pp. 50–58, figs. 2; abs. in Chem. Centbl., 1900, I, No. 4, p. 265*).—The method is based upon the formation of brown solutions by the reaction between nitrates and ferrous sulphate. The determination is made as follows: To 5 cc. of the nitrate solution containing about 8 cc. of concentrated sulphuric acid add a ferrous sulphate solution of known strength, with careful exclusion of air, until the brown coloration no longer disappears on shaking. Add 8 cc. more of sulphuric acid and ferrous sulphate in small amounts until the solution becomes red brown, ascertaining the end of the reaction by testing with potassium ferrocyanid for an excess of ferrous sulphate. Two molecules of nitric acid oxidize 6 molecules of ferrous sulphate. An apparatus suited to the method is described.

Increasing the sensitiveness of the nitric acid reaction with diphenylamin in water examination, R. CIMMINO (*Ztschr. Analyt. Chem., 38 (1899), No. 7, pp. 429–431*).—The reaction is rendered most sensitive by the addition of a few drops of a 5 to 10 per cent hydrochloric acid solution, in which case the whole solution is colored blue, and no attention need be paid to the time of contact of the water and reagent. The reaction is sensitive in 1 part of nitric acid in 1 million of water. No other constituent in water was found to give the reaction.

The meaning of the acetyl value in fat analysis, J. LEWKOWITSCH (*Analyst, 24 (1899), Dec., pp. 319–330*).—The paper records certain precautions to be observed in the determinations, especially the necessity for avoiding the presence of carbon dioxid in the water used. It is shown that the filtration and distillation processes yield concordant results, especially in the case of oils carrying only small amounts of volatile acids. Fats carrying large proportions of fatty acids are more conveniently examined by the distillation process.

A series of analyses indicates that exposed or rancid fats have a higher acetyl value than fats in a fresh state. The acetyl value can not yet be considered a constant.—G. W. SHAW.

Detection of cotton-seed oil in oils, butter, and lard, J. WAUTERS (*Bul. Assoc. Belge Chim., 13 (1899), No. 10, pp. 404–416*).—The author reviews the Becchi test, but concludes that Halpens' reaction is preferable because it gives no red coloration with other oils, butter, lard, etc. The reaction is delicate, and allows 0.25 per cent of cotton-seed oil to be detected in a mixture. Old cotton-seed oils also respond to the reaction. It is possible, by comparison, to determine the approximate amount of cotton-seed oil in a mixture by means of this test. The test is as follows: Equal volumes of the oil in question, amyl alcohol, and carbon bisulphid containing 1 per cent of sulphur in solution, are heated in a tube in a saline bath for 10 or 15 minutes. A red or orange coloration denotes the presence of cotton-seed oil.—H. SNYDER.

An accurate and practical method of determining the fat content of cream, V. Dehlholm (*Mälkeritid., 12 (1899), No. 18, pp. 313–319*).—The author recommends diluting the cream with a weighed quantity of water sufficient to make the fat content of the mixture from 6 to 8 per cent, and then determining the fat content by the Gerber method. Comparative determinations showed the results obtained in this way to be slightly too low, the error varying with the richness of the cream, and a table for correcting the results was accordingly worked out for cream containing from 12.5 to 49 per cent of fat, and is given in the paper. The dilution with water offers no difficulty in case of thin cream; to avoid formation of foam in case of cold, rich cream, it is warmed on a water bath for 5 minutes at 69° C. prior to the dilution with water.—F. W. WOLL.

Emil Wolff's treatise on the chemical investigation of materials important in agriculture, E Haselhoff (*Emil Wolff's Anleitung zur chemischen Untersuchung landwirtschaftlich wichtiger Stoffe. Berlin: Paul Parey, 1899, 4. ed. rev., pp. X+186, figs. 17*).—A thoroughly revised edition of this well-known work. It gives methods of examination of water, soils, manures and fertilizers, ashes, feeding stuffs, milk and creamery products, eggs, seeds, etc.

Quantitative chemical analysis, N. Knight (*New York: A. S. Barnes & Co., 1899, pp. 110*).—This volume contains general suggestions on the methods of procedure in organic analysis; detailed directions for the gravimetric analysis of 15 substances; a chapter on volumetric analysis; and the analysis of drinking water. A number of tables of constants useful in calculating the results are also included. According to the author "the course marked out in these pages will constitute a sufficient basis for advanced work in organic chemistry, including the ultimate analysis of substances by combustion, and for industrial chemistry which requires quantitative methods."

Introduction to micro-chemical analysis, H. Behrens (*Anleitung zur mikrochemischen Analyse. Leipsic: L. Voss, 1899, 2. ed., pp. XI + 242, figs. 96; rev. in Oesterr. Chem. Ztg., 3 (1900), No. 3, p. 59*).

Report of the chemist, R. H. Forbes (*Arizona Sta. Rpt. 1899, pp. 228–234*).—A summary account of the work of the year in this department of the station, including examinations of sugar beets and waters (E. S. R., 11, p. 236), soils, cañaigre, etc.

Miscellaneous analyses, H. Snyder (*Minnesota Sta. Bul. 63, pp. 495–512*).—Analyses are reported of various foods, food preservatives, and feeding stuffs (see p. 883); fertilizing materials (see p. 831); and miscellaneous substances, including water for retting flax, limestone for refining beet sugar, a germicide for hog cholera, insecticides, and a weed exterminator.

Chemical department, E. F. Ladd (*North Dakota Sta. Rpt. 1898, pp. 10–21*).—This is in the main a synopsis of the work of the department, on drinking waters, wool scouring, soil, humus, feeding stuffs, vinegars, poisoning of cattle by water hemlock, a glucosid of millet hay, sugar beets and preserving eggs, previously noted in E. S. R., 10, pp. 129, 171, 181, 194; 11, pp. 214, 241, 279, 287; and on chicory, marl, and ripening of cream, already noted in E. S. R., 10, p. 715; besides a record of observations on soil temperature and moisture (see p. 823), temperature of the air, and rainfall (see p. 821).

Report of the chemist, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 123–125*).—A synopsis of the work of the year in this department.

On acidimetry, H. IMBERT and A. ASTRUC (*Compt. Rend. Acad. Sci. Paris, 130 (1900), No. 1, pp. 35–37*).

The official methods for fertilizers and feeding stuffs of the Belgian laboratories and the agricultural stations of Holland and the Grand Duchy of Luxemburg (*Ann. Sci. Agron., 1899, II, Nos. 1, pp. 159, 160; 2, pp. 161–172*).—See also E. S. R., 11, p. 104.

On the distinction between citrate-soluble phosphoric acid according to the older and more recent methods and citric-acid-soluble phosphoric acid (*Deut. Landw. Presse, 27 (1900), No. 3, p. 28*).—Brief remarks on this subject.

The separation of tungsten and molybdenum, F. IBBOTSON and H. BREARLEY (*Chem. News, 81 (1900), No. 2094, pp. 13–15*).

The determination of alkalis in spring water, E. BOHLIG (*Ztschr. Analyt. Chem., 38 (1899), No. 7, pp. 431, 432*).—A short description of methods for determining the alkalis and alkaline earths.

Silica standards for the determination of turbidity in water, G. C. WHIPPLE and D. D. JACKSON (*Tech. Quart., 12 (1899), No. 4, pp. 283–287*).

A new method for determining iron in organic substances, F. RÖHMANN and F. STEINITZ (*Ztschr. Analyt. Chem., 38 (1899), No. 7, pp. 433–435*).

Determination of sulphur in organic substances, R. HENRIQUES (*Chem. Ztg., 23 (1899), No. 81, p. 869*).

Detection of fluorin in wine, G. PARIS (*Chem. Ztg., 23 (1899), No. 67, pp. 685, 686*).—Description of methods.

Color analysis of food preparations, S. WEISSBEIN (*Farbenanalytische Untersuchungen über Nahrpräparate. Inaug. Diss., Berlin, 1899; abs. in Chem. Centbl., 1899, I, No. 20, pp. 1114, 1115; Ztschr. Untersuch. Nahr. u. Genussmtl., 3 (1900) No. 1, pp. 41, 42*).—The results are reported of the examination of a number of prepared foods by means of the Erlich-Biondi tricolor mixture, according to Posner's method.

Honey analyses, C. HOITSEMA (*Ztschr. Analyt. Chem., 38 (1899), No. 7, pp. 439–441*).—The author gives the results of analyses of 10 samples of honey of "unquestionable purity," describing the methods employed.

The estimation of albumoses and peptone, J. EFFRONT (*Bul. Soc. Chim. Paris, 3. ser., 21 (1899), No. 14, pp. 680–683; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 3 (1900), No. 1, p. 39*).

The cleavage of carbohydrates from protein, O. WEISS (*Centbl. Physiol., 12 (1898), pp. 515, 516; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 12, p. 920*).—A preliminary communication.

Analytical methods for distinguishing between nitrogen of proteids and nitrogen of simpler amids or amido-acids, J. W. MALLET (*Chem. News, 80 (1899), Nos. 2080, pp. 168–171; 2081, pp. 179–182*).—This paper has been abstracted from the original source (E. S. R., 10, p. 819).

Modification of the method of Mörner and Sjöquist for determining urea or the nitrogen of urea, H. MORREIGUE (*Jour. Pharm. et Chim., 6. ser., 8 (1899), No. 5, pp. 193–197*).

The iodin number of fatty acids, A. ZEGA and R. MAJSTOROVIĆ (*Chem. Ztg., 23 (1899), No. 57, p. 597*).

On a possible source of error in the Gerber method of fat determination, M. SIEGFELD (*Molk. Ztg., 13 (1899), No. 28, pp. 433–435*).—The results of a series of experiments agree with the conclusions reached by Richmond and O'Shaughnessy (E. S. R., 11, p. 213) that in the Gerber test the sulphuric acid, milk, and amyl alcohol should be added in the order named.

On the detection of margarin, H. Bremer (*Milch Ztg., 28 (1899), No. 49, pp. 769–771*).—The literature on tests for margarin is reviewed and the reliability of the sesame-oil reaction discussed.

Examination of cotton-seed oil for adulteration with maize oil, G. Morpurgo and A. Götze (*Oesterr. Chem. Ztg., 3 (1900), No. 3, pp. 53, 54*).

On the constitution of starch, I, W. Syniewski (*Liebig's Ann. Chem., 309 (1899), p. 282; abs. in Chem. Ztg., 23 (1899), No. 96, Repert., p. 348*).—In this number the author summarizes the previous investigations on different kinds of starch.

On a crystallized fibrin, L. Maillard (*Compt. Rend. Acad. Sci. Paris, 130 (1900), No. 4, pp. 192–194*).

Observations on the work of Bode and Kohl on chlorophyll, L. Marchlewski (*Jour. Prakt. Chem., n. ser., 61 (1900), No. 1, pp. 47–63*).

"Perezol," a new indicator, M. Duyk (*Bul. Assoc. Belge Chim., 13 (1899) No. 11, pp. 461–466*).—The origin of this compound, the color which it produces with alkalis, and its merits as an indicator are discussed. Its solubility in fatty bodies gives it certain advantages over other indicators in the determination of fatty acids and in general food investigations.—H. Snyder.

An improved Soxhlet reflux condenser of glass, C. Kob & Co. (*Ztschr. Analyt. Chem., 38 (1899), No. 7, pp. 442, 443, fig. 1*).—The cooler consists of 3 concentric bulbs, the outer and inner being connected with running water, and the condensation of the ether taking place in the space between these two.

BOTANY.

The structure of the cells of vessels, W. Rothert (*Bul. Internat. Acad. Sci. Cracovie, 1899, pp. 15–53, pls. 2, figs. 7; abs. in Jour. Roy. Micros. Soc. [London], 1899, No. 3, pp. 292, 293*).—The author claims that the ordinary classification of vessels into spiral, annular, reticular, and those with bordered pits is founded on an erroneous view as to their origin. The essential structure of the membrane is the same for all vessels and all are characterized by the presence of bordered pits. The author classifies them under 2 principal heads, according as they are extensible or not. The first kind, which includes annular and spiral vessels, are characterized by the thin parts of the wall running continuously around the vessel while the thicker parts are not connected longitudinally. Hence the membrane is capable of longitudinal stretching and, under certain circumstances, the thickened portion may become detached. In the second group the thin portions of the membrane are not continuous, while the thickened parts are connected in all directions into a network. The author insists that there is uniformity in the physiological purpose of all kinds of vessels. The thin portions permit the passage of water between the vessels and the surrounding elements, while the thickened portions enable them to resist radial pressure.

The chemical energy of living cells, O. Loew (*Die chemische Energie der lebenden Zellen. Munich, 1899, pp. 175; abs. in Jour. Roy. Micros. Soc. [London], 1899, No. 5, p. 498*).—In this work the author discusses the energy of living protoplasm, giving the result of a large number of his observations. The present volume treats of the causes of vital activity, the general characteristics of living substance, its chemico-physiological characteristics, the essential accompaniments of protoplasm, the character of bio-chemical work,. the formation of albumin in the lower fungi and in chlorophyllous plants, the theory of the formation of albumin, a transient protein substance as a reserve-substance in plants, the chemical characteristics of proto-protein, the motility and activity in protoplasm, and the theory of respiration. It is stated that the motility of protoplasm is brought about by the concurrence of aldehyde and amid groups, and that the oxydases can not be regarded as the source of respiration.

Absorption of solutions by the stems of plants, E. BRÉAL (*Ann. Agron., 25 (1899), No. 10, pp. 449-458*).—By means of capillary tubes thrust into the stems and leaves of maize, white lupines, chestnut, willow, amaranths, and Jerusalem artichokes, the author has sought to ascertain the possibility of the absorption of manganese nitrate and sulphate, nitric acid, ammonium nitrate and sulphate, and potassium humate.

It was found that these substances could be absorbed at the pleasure of the investigator. Manganese was readily absorbed by plants which were formerly without trace of it as was shown by the incineration of leaves and branches. Nitric acid in the form of nitrates was taken up by the stem of maize. Ammonium sulphate was taken up by the same plant, but not in a sufficient amount for quantitative determination. The nitric acid accumulated in the tissue of the maize as reserve material, while ammonia was transformed as soon as it entered the plant. Ammonium carbonate was absorbed by the leaves of hollyhocks and the stems of artichokes. Willow and chestnut leaves, previously without a trace of nitrates, absorbed considerable quantities of nitrates. Amaranths, already containing a large quantity of nitrate, greatly increased their content during the experiment. Potassium humate was taken up by lupines and was optically apparent in the woody tissues as well as in the intercellular spaces. In the experiments with maize, the entrance of humic acid was accompanied by the disappearance of nitric acid. In the experiments with amaranths, there was a reduction of nitric acid when humic acid was present, but not a total disappearance. The combination of humic and nitric acids in lupines resulted in an appreciable increase in the dry matter of the plants.

The influence of light on the growth of clover, A. PAGNOUL (*Ann. Agron., 25 (1899), No. 8, pp. 353-356*).—The growth and transpiration of crimson clover as affected by strong light and shade were investigated by means of a balance provided with a Richard register. Equal lots of seed were grown in pots containing the same amount and kind of soil, the only difference being in the amount of light. A short distance above one pot a black shade was suspended in such a way as to intercept all solar rays and maintain the plant in semidarkness without in any way interfering with the free exchange of air. The plants were always kept in a humid atmosphere and the transpiration from the well-lighted plants was always in excess of that from shaded plants. Their growth was strikingly unlike. The well-lighted plants were strong and their leaflets hairy, while the others were weak, long petioled, and smooth. At irregular intervals 100 plants were taken from each lot, dried, and analyzed, with marked differences in dry matter in favor of the plants grown in the unimpeded light. The nitric nitrogen per hundred grams of dry matter was greater in the shaded plants, showing that the nitrates accumulated in the shaded plants on account of the inability to assimilate them and, as a consequence, their development was retarded. In the plants grown under the direct action of the solar rays, nitric nitrogen was present in an appreciable quantity at the beginning of the experiment, but after about a month all trace of it had disappeared.

The author concludes that nitrates are reduced in the leaves under the action of the sun, and furnish the necessary nitrogen for the formation of albuminoid principles required by the plant.

Soil inoculation for the growth of legumes, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 137-142*).—An account is given of pot and plat experiments with peas, beans, and clover to test the value of Nitragin as an inoculation material.

In the pot experiments with peas, the author again arrived at the conclusion expressed in a previous report (E. S. R., 10, p. 845), that the larger amount of nitrogen in the treated crop is due to the greater development of root or foliage, or both, under the stimulating effect of micro-organisms furnished by the preparation.

In the case of the horse bean experiments, the largest yield was obtained from the soil-inoculated plants, and the smallest from the plats where the seed had been inoculated.

In the plat experiments the crop of clover from inoculated seed was much more luxuriant than that from the untreated seed, and, as shown by the tables, the yield was considerably heavier. With horse beans and peas in pots, the results were not so encouraging.

Summarizing the results of the year's work with Nitragin, the author states that on the whole the experiments confirm the previous results and furnish further evidence of the usefulness of this agent in fostering the growth of leguminous plants.

The real meaning of plant acclimatization, V. POLOVTSEV (*Selsk. Khoz. i Lyesov., 194 (1899), Sept., pp. 477-492*).—The term acclimatization is often misunderstood and misapplied. According to the author, by the acclimatization of a plant is understood its complete adaptation to new conditions, brought about by corresponding changes in its organization. Moreover, acclimatization can be considered as complete only in those cases where the introduced plant proves capable of completing under the new climatic conditions its full cycle of development, *i. e.*, not only of maintaining its own existence but of reproducing vigorous descendants. Such requirements, it is claimed, are very rarely fulfilled. For example, cucumbers, watermelons, and cantaloupes whose home is southern Asia and northern Africa, and which have been for a very long time cultivated in Europe, reach full maturity and produce healthy seed, but only with the aid of man. When left to themselves they invariably perish, the fruit rotting away in a rainy fall, and the occasional spring sprouts are killed by the frosts.

In the case of "naturalized" plants, although often coming from distant regions, they are introduced into countries with climatic conditions similar to those of their native land.

Real artificial acclimatization is a very rare thing. In most cases reported of the rapid acclimatization of a plant one of two things has taken place, either the plant has been naturalized or its acclimatization is not complete, the newly introduced plant not being capable of producing vigorous offspring.

Artificial acclimatization is only possible within very narrow limits. All that can be accomplished is to move a plant a little way beyond its climatic boundary, to somewhat lengthen or shorten the period of vegetation of an annual plant, or to adapt a plant from a more humid climate to a drier one, and conversely. This can be achieved only by means of the gradual, careful, and more or less protracted selection of the more enduring individuals.—P. FIREMAN.

Department of botany, H. L. BOLLEY (*North Dakota Sta. Rpt. 1898, pp. 24–28*).—The lines of work carried on by the botanical department of this station embrace investigations of rusts and smuts of cereal grains, studies of the native flora of the State, bacteriological investigations of the relationship of typhoid fever to the dairy industry, and miscellaneous histological and mycological studies pertaining to the determination of the relationship of certain parasites to their hosts.

Ferns and flowering plants of South Dakota, D. A. SAUNDERS (*South Dakota Sta. Bul. 64, pp. 101–227*).—This catalogue of species is based upon specimens in the college herbarium and on notes made by the author and the former botanist of the station, T. A. Williams.

Recent observations on Amphicarpæa monoica, ADELINE F. SCHIVELY (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 20–30*).—The present paper continues previous observations on the life history of this plant, in which the relation between the normal and cleistogamic flowers is studied.

Observations on Conopholis americana, LUCY L. W. WILSON (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 1–19, pls. 6*).—This interesting plant, the author states, is parasitic on the oak, and often forms a fringe of growth around the trunk for a distance of 10 ft. or. more. It first attacks young roots and usually starves the portion beyond the point of infection. It is perennial to the extent of living at least 8 or 10 years. The union between the parasite and host is said to be an extremely intimate one, the parasite being practically developed within the host, which rises up and incloses it after germination. The irritant action of the parasite causes the swelling of the host root and the enormous multiplication of its sclerenchyma. Numerous other points of interest in the anatomy of the plant are discussed.

Observations on some hybrids between Drosera filiformis and D. intermedia, J. M. MACFARLANE (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 87–99, pl. 1*).

Grass garden, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1899, pp. 209–214*).—A report is given of the condition of a grass garden in which a large number of native grasses are compared. The different species, to the number of about 100, are briefly commented upon, and it is the expectation of the author to give an illustrated report of those which appear to be the most valuable.

Statistical information concerning the production of fruits and seeds in certain plants, J. W. HARSHBERGER (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 100–109*).—The author has reported observations made upon quite a number of plants to determine the relative ratio between the perfect and abortive seeds and fruits, in order that some idea might be obtained as to the success of pollination and fertilization.

The plants reported upon are Indian turnip, pinxter flower, flowering dogwood, American bladder nut, *Hibiscus moscheutos*, *Xanthium canadense*, *Yucca filamentosa*, and *Pimpinella integerrima*.

From the tabular statements given, it appears that in a number of instances the number of abortive seeds and fruits greatly exceeded the perfect ones.

Water storage and conduction in Senecio præcox, J. W. HARSHBERGER (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 31–40, pls. 2, fig. 1*).—This plant, which is abundant in the valley of Mexico, is protected from rapid transpiration in a rather unusual manner. The bark of the plant consists of tabular cells arranged in a number of layers outside the cortex. Prominent in the cortex are found reservoirs filled with a balsam-like fluid which hardens upon exposure to the air. When a stem is cut or injured this liquid exudes, hardens, and thus closes the wound. The structure of the pith of the plant is figured and described, from which it appears that the water-storage reservoirs of the plant are in this region.

Observations on the development of some embryo sacs, R. E. B. MCKENNEY (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 80–86, pl. 1*).

Structure and development of the internal phlœm in Gelsemium sempervirens, CAROLINE B. THOMPSON (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 41–54, pl. 1, fig. 1*).

The structure of the cork tissues in roots of some rosaceous genera, MARTHA BUNTING (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 54–65, pl. 1*).

Comparative studies on the rate of circumnutation of some flowering plants, ELIZABETH A. SIMONS (*Contrib. Bot. Lab. Univ. Pennsylvania, 2 (1898), No. 1, pp. 66–79*).

On the distribution and biological importance of furfuroids in the soil, J. STOKLASA (*Sitzber. Math. Naturw. Cl. K. Akad. Wiss. [Vienna], 107 (1898), No. 8, pp. 966–976*).—Furfuroids in the soil are essential to the development of the bacteria concerned in nitrogen assimilation.

METEOROLOGY—CLIMATOLOGY.

Monthly Weather Review (*U. S. Dept. Agr., Weather Bureau, Monthly Weather Review, 27 (1899), Nos. 10, pp. 449–502, pl. 1, figs. 3, charts 9; 11, pp. 503–533, charts 9; 12, pp. 535–575, fig. 1, charts 10*).—In addition to the usual reports on forecasts, warnings, weather and crop conditions, meteorological tables and charts, No. 10 contains special contributions on Effect of wind on catch of rainfall, by G. J. Symons; Description of a new brass river gauge at Richmond, Va., and its method of support, by O. D. Leisenring; The climate of St.

Lawrence Island, by A. J. Henry; The sluggishness of thermometers (illus.), by C. F. Marvin, and Serpentine lightning, by J. W. Kales; and notes by the editor on the rain gauge and the wind, meteorology by the laboratory method, the recurving of hurricane tracks in the North Atlantic, meteorology in the schools, replies to correspondents regarding thunderstorms, tornadoes, and danger from lightning, the baguios of the Philippines, the Ben Nevis observatory, the Seventh International Geographical Congress, The Weather Review and the high schools, heat radiation of the stars, the first volume of the Maryland Weather Service, the director of the Iowa Weather and Crop Service, rainfall and rivers in Idaho, irrigation by wire, auroras in Texas, frosts and strawberry crop, warm rains and angleworms, this year's crop and last year's growing season, protection against frost, the weather and the dairy, losses by lightning, vapor pressure for water and ice, and temperature and moisture of soils in Red River Valley.

No. 11 is confined to the usual reports, with no special articles.

No. 12 contains special contributions on Ratio of the discharges of the Chagres River at Gamboa and Bohio to the rainfall in the watershed above these places (illus.), by H. L. Abbott; Comparative rain gauge readings at Atlanta, Ga., by A. J. Henry, and Date of cold Friday, by A. J. Henry; and notes by the editor on history of the barometer, "tule fog," the "Gran Cultura" in Puerto Rico, scientific assistants, barometric corrections and reductions, meteorology in the universities, and meteorological observations at public schools.

Meteorological observations, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1898, pp. 213–215*).—A record is given of observations on temperature, pressure, humidity, precipitation, cloudiness, and wind movement during each month of 1898 at Storrs, and on rainfall during the 6 months ended October 31, 1898, at 21 points in Connecticut. The mean temperature at Storrs for the year was 48° F.; mean pressure, 30.04 in.; total rainfall, 51.13 in.; number of cloudy days, 128. The average rainfall for the State during the 6 months ended October 31 was 29.54 in. The rainfall was 5.3 in. above the average at Storrs for the past 10 years, and about 3 in. above the general average for Connecticut. It was fairly well distributed throughout the year. The temperature for April and May was unusually low. The last killing frost occurred on May 10. The summer was unusually warm and the weather conditions were favorable for nearly all crops.

Work at the station of agricultural climatology of Juvisy during the year 1898, C. FLAMMARION (*Bul.* [*Min. Agr. France*], *18 (1899), No. 3, pp. 150–169, pls. 7, figs. 7*).—The work here reported, which was mainly a continuation of that of previous years (E. S. R., 10, p. 613) included observations on temperature of the air and of the soil at different depths, atmospheric pressure, solar radiation, rainfall, underground water, and photography of atmospheric phenomena.

The temperature for each day of 1898 is reported, as well as the means for 14 years (1885–1898). The results are platted for the year and for the seasons and discussed in some detail. The mean temperature for the year 1898 was 10.7° C.

The observations on the temperature of the soil were of the same character as those of previous years and gave similar results.

Observations on solar radiation were continued with the form of actinometer described in the previous report (E. S. R., 9, p. 616). The results are given in tables and diagrams. The sunshine recorded was 1,540 hours and 45 minutes; the calories, 123,269.

The rainfall was 539.1 mm. in 1898. A diagram shows the rainfall at Paris since 1690. The temperature of the rainfall was also taken and compared with that of the air. The temperature of the rain was uniformly lower than that of the air. The number of days on which rain fell was 136.

The observations on underground water and the results obtained were of the same nature as those recorded in 1897. The results of work on cloud photography are reported with some excellent reproductions of cloud photographs.

The diagrams accompanying this report are very ingenious and instructive.

Studies of the atmosphere by means of meteorological instruments carried by kites, L. TEISSERENC DE BORT (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 2, pp. 131, 132*).—A brief account is given of observations made at Trappes in 1897, 1898, and 1899. By means of Hargrave kites observations were made at heights of over 3,000 meters. It was observed that with clear weather and high pressure the force of the wind decreased with the altitude up to a height of 1,500 to 3,000 meters, but that the opposite was true when the weather was cloudy and the pressure low. Within certain limits of altitude the temperature fell very slowly and sometimes increased with the altitude in zones of high pressure. In zones of low pressure the fall in temperature was more rapid.

Meteorological observations, W. F. ELLIS, R. ROBERTSON, and A. MACKAY (*Canada Expt. Farms Rpts. 1898, pp. 72, 241, 242, 373*).—Summaries of observations on temperature, sunshine, and precipitation at the Central Experimental Farm at Ottawa for each month of 1898; general notes on the weather and a monthly summary of observations on temperature for the year ended November 30, 1898, at Nappan, Nova Scotia; and a monthly summary of observations at Indian Head, Northwest Territories, on temperature, sunshine, and precipitation during the year ended November 30, 1898.

Summary of meteorological observations, 1899 (*Colonia, 5 (1899), No. 6, p. 357*).—This is a monthly summary of observations on temperature, rainfall, sunshine, and direction of the wind made at Colonial College, Hollesley Bay, Suffolk, England.

Meteorological summary for 1898 (*Maryland Sta. Rpt. 1899, p. VII*).—A monthly summary of observations on temperature and precipitation. The highest temperature was 105° F., July 2; the lowest, 4°, Dec. 15; the mean, 50.2°. The total annual precipitation was 35.24 in.

Meteorological report, J. S. Moore (*Mississippi Sta. Rpt. 1898, pp. 10, 11*).—This is a summary of the monthly precipitation during 1897 and 1898, with an average for 10 years. The relation of the distribution of the rainfall to the growth of crops during 1897 and 1898 is briefly discussed.

Some studies in meteorology, E. F. Ladd (*North Dakota Sta. Rpt. 1898, pp. 13-18, 20*).—Monthly summaries of observations on temperature and rainfall for 7 years (1892-1898). The average rainfall at Fargo for 7 years was 19.72 in.

Meteorology of the year 1899 (*Rev. Sci.* [*Paris*], *4. ser., 13 (1900), No. 4, pp. 119-121*).—Observations made in France and other parts of Europe and in North Africa are summarized and discussed.

The station of agricultural climatology at Juvisy, 1894, C. Flammarion (*Ann. Sci. Agron., 1899, II, No. 1, pp. 1-37, figs. 16*).

The movements of the air, E. Less (*Noted in Rev. Sci.* [*Paris*], *4. ser., 12 (1899), No. 23, p. 729*).

Explosions to prevent hailstorms, J. Dufour (*Chron. Agr. Canton Vaud, 13 (1900), No. 1, pp. 1-12, figs. 2*).—A more complete account of what purport to be successful experiments in Styria, briefly noted in E. S. R., 11, p. 323, with descriptions of the apparatus and methods used.

Protection against tornadoes, H. A. Hazen (*Amer. Agr. (mid. ed.), 65 (1900), No. 3, p. 68*).

Frost warnings and protection, J. W. Smith (*Amer. Agr. (mid. ed.), 65 (1900), No. 3, p. 82*).—An address delivered before the Ohio Board of Agriculture, January, 1900.

Climate and plant growth in Argentina (*Mitt. Deut. Landw. Gesell., 14 (1899), No. 20, Sup., pp. 113-120; No. 21, Sup., pp. 124-128*).

Kite meteograph construction and operation (*Sci. Amer. Sup., 49 (1900), No. 1258, pp. 20166, 20167, figs. 4*).

WATER—SOILS.

A study of the phosphoric acid dissolved in the soil water, T. Schloesing (*Ann. Sci. Agron., 1899, I, Nos. 2, pp. 316-320; 3, pp. 321-359, figs. 8*).—A detailed account of investigations briefly reported elsewhere (E. S. R., 10, p. 714). Examinations were made of 8 good soils of very different character. In all of these the phosphates, although very slightly soluble, were nevertheless dissolved in small proportions in water, the amount so dissolved varying from 0.1 to 3 mg. per liter, but was remarkably constant for one and the same soil. It was found that the proportion of phosphoric acid soluble in water remained comparatively constant in spite of the fact that considerable amounts were withdrawn by the roots of plants. On the basis of experiments with a variety of crops grown in pots it is estimated that during the 25 or 30 weeks of the growing period the soils furnished in this way from 10 to 30 kg. of phosphoric acid per hectare. It thus appears that while the amount of phosphoric acid present in the soil water at any given time is comparatively insignificant, the total amount which may thus be furnished to plants during the growing period becomes a factor of first importance.

On the solubility of the phosphoric acid in the surface soil and subsoil, J. SEISSL (*Ztschr. Landw. Versuchw. Oesterr., 2 (1899), pp. 120–124; abs. in Chem. Centbl., 1899, II, No. 21, p. 1136; Chem. Ztg., 23 (1899), No. 40, Repert., p. 149*).—The results of examinations of 12 samples of soil (surface and subsoil) for total phosphoric acid and sesquioxids and citric-acid-soluble phosphoric acid are reported. The results show that the relation between phosphoric acid and sesquioxids was much closer in the surface soils than in the subsoils and that the phosphoric acid of the former was more soluble than that of the latter. The citrate solubility is very largely determined by the amounts of sesquioxids and organic matter present, but the lime content also undoubtedly exerts an influence in this respect.

What percentage of phosphoric acid should a good soil contain? A. PAGNOUL (*Ann. Agron., 25 (1899), No. 11, pp. 519–557, fig. 1*).—The author reports pot experiments with crimson clover on 2 soils (each a mixture of a number of soils), 1 of which contained 89 mg. of total phosphoric acid and 0.13 mg. of assimilable phosphoric acid, and the other 160.5 mg. total phosphoric acid and 6.18 mg. of assimilable phosphoric acid per 100 gm. of soil. One pot of each soil (6 kg.) received no fertilizer, while one received 3 gm. of superphosphate. From a study of the weight and composition of the crops obtained the author concludes that for clover at least the commonly accepted limit of 0.1 per cent of phosphoric acid in soils is too low and should be raised to from 0.15 to 0.2 per cent. The question, however, demands further study.

The method employed by the author in examining soils for available phosphoric acid is as follows: Treat an amount equal to 10 gm. of dry soil for 2 hours with 10 cc. (diluted to 50 cc.) of a solution of acetic acid prepared by dissolving 120 gm. of crystallized acetic acid in 1 liter of water, a sufficient additional quantity of the acetic acid solution being added to neutralize the lime present in the soil, and the solution shaken 10 times during the process. Use 25 cc. of the filtered solution, corresponding to 5 gm. of the soil, for the determination of phosphoric acid. For this purpose the author uses a colorimetric method which requires the following solutions: (1) A solution of 100 cc. of ordinary ammonia diluted to 1 liter; (2) 70 to 80 cc. of sulphuric acid diluted to 1 liter; (3) a 10 per cent solution of potassium ferrocyanid; and (4) a type solution of phospho-molybdate containing 4 mg. of phosphoric acid per liter, prepared as follows: A solution of sodium or ammonium phosphate containing exactly 4 mg. of phosphoric acid is precipitated in the form of phospho-molybdate, the precipitate washed on a filter to remove all excess of ammonium molybdate, and then dissolved in the ammonia solution above described, the volume being made up to 1 liter with the same solution. The determination of phosphoric acid in soil is made by dissolving the precipitate obtained from 25 cc. of the acetic-acid solution in the ammonia solution and comparing the color with that of the type solution of phospho-molybdate.

Soil temperature and moisture, E. F. LADD (*North Dakota Sta. Rpt. 1898, pp. 14–18, 20, 21*).—This is a record of observations on soil temperature at depths of 1 to 84 in. during the period from May, 1892, to December, 1898, inclusive, and on soil moisture as determined weekly in a cultivated field at the college during May–October for 5 years (1892–1896). From data obtained during 1893–1897 it appears that the frost lines in an open field at Fargo was between 4 and 5 ft. As a rule the frost was found to be out of the ground by May 20.

The mean monthly temperatures at different depths during 7 years (1892–1898) are shown in the following table:

Mean monthly temperatures for 7 years (1892–1898).

Month.	1 inch.	3 inches.	6 inches.	12 inches.	24 inches.	48 inches.	60 inches.	84 inches.
	Degrees.	*Degrees.*	*Degrees.*	*Degrees.*	*Degrees.*	*Degrees.*	*Degrees.*	*Degrees.*
May	56.6	50.8	46.8	43.9	38.7	34.3	33.7	34.8
June	67.0	61.9	58.8	57.6	51.0	44.0	40.9	38.0
July	74.1	67.9	65.2	63.6	59.3	53.1	49.1	43.7
August	75.6	66.2	64.5	63.5	61.0	56.0	52.9	47.4
September	67.1	60.4	57.5	58.4	57.8	55.7	53.9	49.6
October	48.6	45.8	46.2	48.5	49.8	51.3	51.2	49.5

"An inspection of the above table shows the 1 in. thermometer to give the highest record in August, while the soil at 3, 6, and 12 in. reaches its maximum temperature in July, the soil at 24 and 48 in. reaches an average maximum in August the same as for the surface soil at 1 in. in depth, while the soils at a depth of 60 and 84 in. continued to grow warmer and reached their maximum temperature in September."

Soil temperatures at Fargo are compared with those observed at Geneva, N. Y. In connection with the record of the amounts of water in the soil during the growing period the yields of various crops on the soil are reported.

Notes on alkali soil in Montana, F. W. TRAPHAGEN and W. M. COBLEIGH (*Jour. Amer. Chem. Soc., 21 (1899), No. 9, pp. 753–757*).—Analyses of typical alkali soils of the Yellowstone Valley are reported for the purpose of showing the kinds of salts usually present, their relative proportions, and their movement in the soil under irrigation. (See also E. S. R., 11, p. 223). The alkali of Montana is almost entirely of the "white" variety.

"With the advent of irrigation, the salts, usually deeply located, begin to rise to the surface. The water table, formerly many feet deep, approaches nearer and nearer to the surface, and of course brings the soluble salts with it. . . .

"The best method for combating the evil would appear to be underdrainage, but land is so cheap that the expense of such a remedy could not be met. Careful surface flooding, economical use of water and intelligent cropping, are the remedies in the hands of the farmer, and properly employed will solve the problem."

Analysis of eastern province soils, C. F. JURITZ (*Agr. Jour. Cape Good Hope, 15 (1899), No. 11, pp. 695–711*).—This is a report of analyses (with descriptions of samples) of 27 samples of soils from Komgha Division, 28 from the Cathcart Division, and 4 from Queenstown Division, of the Province of Cape of Good Hope. This is a continuation of the soil survey of the colony, partial reports of which have already been noted (E. S. R., 11, p. 328). The average composition of the soils examined is as follows:

Average composition of eastern Cape of Good Hope soils.

	Number of analyses.	Fine earth.	In fine earth. Lime.	Potash.	Phosphoric acid.	Nitrogen.[a]
		Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Komgha	27	97.0	0.126	0.061	0.027	0.182
Cathcart	28	94.3	.165	.109	.042	.101
Queenstown	4	93.8	.280	.171	.028	.100

[a] In soil passing 1 mm. sieve.

"Taken all round there is a fair amount of lime and potash in the soils of both divisions [Komgha and Cathcart], but they are decidedly poor in phosphates."

Analysis of Transkei soils, C. F. Juritz (*Agr. Jour. Cape Good Hope, 15 (1899), No. 12, pp. 777–781*).—Samples of 16 soils from the Butterworth, Willowvale, and St. Mark's divisions of the Colony are described and analyses of them reported. This work was done in continuation of the soil survey of the Colony, partial reports of which have already been noted (see above). The average composition of the soils is as follows:

Average composition of western Cape of Good Hope soils.

	Number of analyses.	Fine earth.	In fine earth Lime.	Potash	Phosphoric acid.	Nitrogen.[a]
		Per cent	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Butterworth	8	93 22	0.107	0 088	0.028	0.166
Willowvale	4	98.57	.041	.159	.045	.158
St. Mark's	4	81 46	.063	.084	.024	.096

[a] In soil passing 1 mm. sieve.

These soils as well as those of other parts of the Colony are especially deficient in phosphoric acid. Some of them are also poor in lime, and potash is present in only fair amounts.

The amount of humus in soils and the percentage of nitrogen in the humus as affected by applications of air-slaked lime and certain other substances, H. J. Wheeler, C. L. Sargent, and B. L. Hartwell (*Jour. Amer. Chem. Soc., 21 (1899), No. 11, pp. 1032–1037*).—This question was studied in experiments with pots filled with soil and subsoil from the experimental plats of the station.

"The pots employed were galvanized iron ash cans about 26 in. deep and 18 in. in diameter, with bottoms inclined toward the center, at which point an opening was left to insure drainage. The pots were set into the soil to within 2 in. of the tops and agricultural drain tiles laid underneath, to prevent the ingress of surrounding soil water. One hundred and fifty-four pounds of subsoil and 100 pounds of surface soil were placed in each pot. The pots were filled in the spring of 1893. In 1893 and 1894 each manured pot received 7.36 gm. of potassium chlorid and 22.07 gm. of dissolved boneblack. In the succeeding years these amounts were increased to 10 and 25 gm., respectively. Wherever nitrogen was applied it was at the rate of 2.65 gm. per pot. Lime, unless otherwise specified, was applied in the form of air-slaked lime, practically free from magnesia, at the rate of 147.2 gm. per pot (4 tons per acre). Gypsum was applied so as to furnish the same amount of calcium oxid as the air-slaked lime at the rate of 4 tons per acre. Rhode Island capped corn (maize) was grown in the pots in 1893, oats in 1894, and spring rye in 1895."

Samples of soil taken after harvesting the rye were examined for humus by treatment with hydrochloric acid according to Hilgard, and with ammonia by Huston and McBride's method. Nitrogen in humus was determined by the Kjeldahl method in the extract obtained by treating the soil with a 2.5 per cent solution of potassium hydroxid. The results were as follows:

Humus and humus nitrogen in limed and unlimed soils differently manured.

Numbers of pots.	Manures applied. *a*	Humus nitrogen in dry soil.	Humus in dry soil.	Nitrogen in dry humus.
		Per cent.	*Per cent.*	*Per cent.*
21	Unmanured	0.130	3.86	3.37
16, 18, 25	Ammonium sulphate	.128	3.93	3.26
15, 22	Ammonium sulphate, air-slaked lime (1 ton per acre)	.133	3.77	3.53
17, 19, 26	Ammonium sulphate, air-slaked lime (4 tons per acre)	.126	3.63	3.47
1, 8	Ammonium sulphate, calcium sulphate (land plaster) at a rate equivalent in CaO to 4 tons of air-slaked lime per acre	.139	3.65	3.81
20, 27	Without nitrogen and lime	.129	3.75	3.44
23, 24	Air-slaked lime (4 tons per acre)	.139	3.51	3.68
6, 13	Sodium nitrate	.143	3.93	3.64
7, 14	Sodium nitrate and air-slaked lime (4 tons per acre)	.183	3.42	3.89

a All of the pots except No. 21 received like amounts of potash and phosphoric acid.

"From the foregoing it will be seen that without exception the addition of air-slaked lime or gypsum resulted in lowering the total amount of humus, as compared with the unmanured plat, yet in every instance the percentage of nitrogen in the humus had been increased. In fact the latter statement applies also even where no nitrogen was added (pots 23 and 24).

"Where lime was not applied, but nitrogen was employed in form of ammonium sulphate, which in the acid soil proved poisonous to plants (pots 16, 18, and 25), it will be observed that the percentage of nitrogen in the humus was even less than where no manure was used (pot 21). On the contrary, where nitrogen in the form of sodium nitrate was added without lime (pots 6 and 13), the percentage of nitrogen in the humus was greater than in the case of the unmanured soil (pot 21).

"It is also of special interest to observe that in the case of the unlimed soil, which received potash and phosphoric acid but no nitrogen (pots 20 and 27), the percentage of humus became less than in the unmanured soil, while, on the contrary, where nitrogen was applied as sodium nitrate and as ammonium sulphate to unlimed soil, it is possible that a slight increase in the percentage of humus resulted. The differences are not great enough, however, to furnish any positive evidence in this respect."

It is suggested that the increase of humus and humus nitrogen in the soils to which nitrate of soda was added was due to "a storage of some of the nitrate nitrogen within the soil in the form of organic matter, which becomes quickly soluble in ammonium hydroxid, or, in other words, passes largely into a condition which permits of its classification with that organic complex which is termed humus."

Well waters from farm homesteads, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 161-165*).—This is a report of analyses with reference to sanitary condition of 75 samples of well water from different parts of the Dominion of Canada, with suggestions as to means of securing a pure water supply on the farm.

Sterilization of drinking water by heat, DESMAROUX (*Stérilisation des eaux d'alimentation par chaleur. Paris: J. B. Baillière & Sons, 1898, pp. 172*).

Irrigation and drainage, F. H. KING (*New York: The Macmillan Co., 1899, pp. XXI+502, figs. 163*).—This book is one of the Rural Science Series, edited by L. H. Bailey. The subjects are discussed from the purely cultural standpoint, and not from that of the engineer, the aim being "to deal with those relations of water to soils and to plants which must be grasped in order to permit a rational practice of applying, removing, or conserving soil moisture in crop production."

The results of the author's own experiments at the Wisconsin Experiment Station, and of his inspection of the irrigation methods of both humid and arid regions in this and in foreign countries, have been freely drawn on in the preparation of this work. It contains chapters on the following topics: General remarks on the importance of water; the extent and geographic range of irrigation; the conditions which make irrigation imperative, desirable, or unnecessary; the extent to which tillage may take the place of irrigation; the increase of yield due to irrigation in humid climates; amount and measurement of water for irrigation; frequency, amount, and measurement of water for single irrigations; character of water for irrigation; alkali lands; supplying water for irrigation; methods of applying water in irrigation; sewage irrigation; principles of drainage; practical details of underdraining. The subject of drainage is briefly treated, occupying only 78 out of the 502 pages of the book.

The value of the White Nile to Egypt, W. WILLCOCKS (*Jour. Khediv. Agr. Soc. and School Agr., 1 (1899), No. 6, pp. 225-231*).—A general discussion of this subject with special reference to the recent decision of the government to appropriate money for the purpose of clearing the sudd from the White Nile, thereby influencing the supply of water available for irrigation purposes.

Influence of forests on underground water, P. OTOTZKY (*Ann. Sci. Agron., 1899, II, No. 2, pp. 300-316, figs. 5*).—In continuation of observations made in 1895 in the steppes (E. S. R., 9, p. 1041) the author in 1897 studied the position of the underground water in forests in northern Russia, where the physico-geographical and climatic conditions are very different from those obtaining in the steppes. The same conclusion, however, was reached as in the former study, viz, that the level of the ground water was always lower in the forest than in adjacent open land.

The soil and water conditions of the province of Rhein-Hessen, of the Rheingau and Taunus, C. LUEDECKE (*Mitt. Landw. Inst. Breslau, 1899, No. 2, pp. 45-149*).—This article describes the typical soil areas of these districts, discusses their geological relations, and reports chemical and mechanical analyses of a large number of samples, with observations on the water relations and spring and underground water of the various soils studied.

Practical treatise on soils; directions for the study, classification, and charting of soils, A. NOWACKI (*Praktische Bodenkunde; Anleitung zur Untersuchung, Klassifikation und Kartierung des Bodens. Berlin: Paul Parey, 1899, 3. ed. rev. and enl., pp. VIII+190, pl. 1, figs. 9*).—This is the third edition, revised and enlarged, of this volume of the Thær-Bibliothek series, the first edition of which appeared in 1884.

Canadian soils, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 154–158*).—This includes reports of partial analyses of 1 sample each of cultivated and virgin soil from Grindstone Island, Magdalen Islands, Quebec, and of 1 sample each of soil from Pefferlaw, Township of Nepean, near Ottawa, and Port Arthur, Ontario, with suggestions as to the fertilizers to be used on these soils.

The geological significance of soil study, E. W. HILGARD (*Science, n. ser., 11 (1900), No. 267, pp. 221, 222*).—A brief note on a paper discussing the value of observations on soil areas and their characteristic vegetation as a means of delineating geological formations, and treating of the chemico-geological relations between soils and the geological formations from which they were derived through subaerial agencies.

Isolation of the organisms of nitrification from soil, V. OMELIANSKI (*Contbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 15, pp. 550–561*).

Soil bacteria, VIBRANS (*Mitt. Deut. Landw. Gesell., 14 (1899), No. 20, pp. 301–303*).

FERTILIZERS.

The preservation of barnyard manure, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 126–137*).—This is a detailed account of investigations already partially reported (E. S. R., 9, p. 822). Particular attention was given to two points in these investigations: (1) a comparison of the changes occurring during the decomposition of protected and exposed manure, and (2) the effectiveness of gypsum as a preservative. In the first case, of 2 lots (4 tons each) of fresh mixed horse and cow manure with litter, alike in composition, one was placed in a closed shed, the other in an open wooden bin with a practically water-tight floor, and both lots were weighed and analyzed month by month for the period of a year. The analytical data obtained include moisture, organic matter, ash, total nitrogen, and nitrogen as ammonia, nitrates, and nitrites, total and available phosphoric acid, and total and available potash. "The amounts of total phosphoric acid and potash obtained were those dissolved out of the manure by hot, strong hydrochloric acid (sp. gr. 1.115) at the temperature of boiling water; the amounts of these constituents designated as available were obtained by treatment with dilute citric acid (1 per cent) in the cold."

From the data obtained, which are reported in full, the following conclusions are drawn:

"(1) There is a greater loss of nitrogen and organic matter from the exposed manure than from that protected. The former lost one-third of its nitrogen, the latter about one-fifth. Ten per cent more organic matter was destroyed in the exposed than in the protected manure.

"(2) There is practically no loss of potash and phosphoric acid from the protected manure.

"(3) The exposed rotting manure lost about one-sixth of its phosphoric acid and somewhat more than one-third of its potash.

"(4) The chief changes, due to fermentation, take place within the first months of rotting, and as far as this experiment goes there is no apparent benefit in rotting for a longer period than 3 months."

"[In the experiments with gypsum] three tons of horse and cow manure, mixed in equal proportions, were allowed to ferment without the addition of any preservative, and an equal weight of the same manure was mixed intimately with ground gypsum or land plaster at the rate of 50 lbs. per ton of manure. These lots were fermented at the same time in separate bins inside the small building used in the previous experiment. The manures were placed in the building on July 15, being then fresh, made as compact as possible and not stirred or otherwise disturbed till the close of the experiment, November 15, when they were again weighed and samples taken for analysis. From time to time both lots of manures were moistened. Both manures, therefore, were, with the exception of the presence of gypsum in the one, rotted under the same conditions."

The results show that the use of gypsum retarded to a certain extent the destruction of organic matter.

"With respect to nitrogen, however, no useful result was observed under the conditions of this experiment from the use of gypsum. The amounts in the manure rotted with and without plaster were practically the same. . . .

"The practical conclusions from this part of this investigation are (1) that the proper place to use gypsum is in the stable, where undoubtedly the greater waste of nitrogen, as ammonia, frequently occurs, and (2) that when the manure heap is kept compact and moist there is not any considerable escape of ammonia."

It was found in these experiments that if the manure is kept moist loss of potash can not be completely prevented without a water-tight, nonabsorbent floor.

Recent studies on the management of manure—loss of nitrogen in the free state, P. P. DEHÉRAIN and DUPONT (*Ann. Agron., 25 (1899), No. 9, pp. 401–420*).—Previous investigations by the authors and others are briefly noted, and an account is given of the changes occurring in lots of manure (372.5 to 527.5 gms.), kept for periods of 8, 22, and 49 days in 1,500 cc. flasks with and without a supply of air. The manure was analyzed at the beginning and end of the experiments and the gaseous products were also collected and analyzed.

The loss of nitrogen in the free state in these experiments varied from 4.9 to 13.4 per cent of the total nitrogen in the manure in case of aerobic fermentation, and from 4.2 to 11.1 per cent in case of anaerobic fermentation. This confirms the conclusions of Dupont[1] and Hébert (E. S. R., 4, p. 589) that manure loses nitrogen in the free state during fermentation. On the other hand, Schloesing (E. S. R., 3, p. 737) has shown that manure may be submitted to fermentation for several weeks without loss of nitrogen in the free state. The results obtained in these experiments indicate that when marsh gas fermentation is energetic there is no evolution of free nitrogen. It is suggested that the best means of promoting this kind of fermentation is to keep the manure very alkaline by frequent wetting with liquid manure. The subject is being further studied on a larger scale.

Recent experiments on the management of stable manure, F. HOLDEFLEISS (*Mitt. Landw. Inst. Breslau, 1899, No. 2, pp. 233–249*).—These experiments were made with zinc-lined wooden boxes containing from 1,580.5 to 1,782 kg. of manure. One box received no preservative, in one 32 kg. of kainit was used, to a third 31 kg. of superphosphate (containing 16 per cent of soluble phosphoric acid) was added. Great care was exercised to secure exclusion of air and uniform wetting of the manure in all cases. The manure was analyzed at the beginning and at the end of the experiment (which lasted about 5 months) with a view to determining the loss of dry matter and nitrogen. Observations were also made on temperature and evaporation. There was a decided loss of organic matter and nitrogen even with the greatest care in packing the manure, keeping it moist, and excluding air. The addition of about 2 per cent of kainit and of superphosphate reduced this loss to a minimum. The kainit was as effective as the superphosphate in preventing loss, and at the same time it allowed very active fermentation to go on, which improved the availability of the fertilizing constituents of the manure.

---

[1] Ann. Agron., 14 (1888), p. 97.

Autumn catch crops—their efficiency as green manure, P. P. DEHÉRAIN (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 3, pp. 139–141*).—This is a discussion based on experiments at Grignon during 1897 and 1898, on the value of vetch as a catch crop to follow wheat and to be turned under as a green manure for potatoes and sugar beets. The growth of vetch varied on the different plats from the equivalent of less than 8 tons to about 16 tons of barnyard manure (with 11 lbs. of nitrogen per ton) per acre. The vetch was turned under at the end of October. All of the plats received an additional application of 12 tons of barnyard manure per acre. With both potatoes and beets the yields were largest on the plats receiving the heaviest green manuring with vetch.

These results confirm those of previous years in demonstrating the great value of autumn catch crops. It is suggested, however, that to get the best results these crops should be turned under in the autumn. If this is delayed until the spring the organic matter will not decompose sufficiently so that the following crop can utilize the nitrogen of the green manure to the best advantage.

Fertilizer inspection, C. D. WOODS and J. M. BARTLETT (*Maine Sta. Bul. 53, pp. 57–70*).—This bulletin is supplementary to Bulletin 50 of the station (E. S. R., 11, p. 137). It gives analyses of 163 samples of fertilizers collected by representatives of the station. The bulletin also includes notes on the valuation of fertilizers and a discussion of the quality of fertilizers offered for sale in Maine.

"A comparison of the results of the analyses of the samples collected by the station with the percentages guaranteed by the manufacturers shows that, while as a rule the fertilizers sold in the State are up to guarantee, in some instances the particular lots of fertilizers sampled are not as good as they should be. The comparisons indicate that many of the manufacturers do not intend to do much more than make good the minimum guarantee, and it is not surprising that this results in some of the goods falling below the guarantee in one or more ingredients."

Analyses and valuations of fertilizers, L. A. VOORHEES and J. P. STREET (*New Jersey Stas. Bul. 139, pp. 59*).—This bulletin gives trade values of fertilizing constituents in 1899 and the results of examinations of the standard commercial materials supplying them, as well as of home mixtures, factory-mixed fertilizers, and miscellaneous fertilizing materials. Analyses and valuations are given of 74 samples of standard raw materials, 321 brands of complete fertilizers, 30 samples of ground bone, 24 samples of home and special mixtures, and 23 samples of miscellaneous products. Materials examined include, in addition to the mixed fertilizers, nitrate of soda, sulphate of ammonia, dried blood, ground fish, tankage, cracklings and hoof meal, ground bone, superphosphates, muriate of potash, sulphate of potash, and kainit. The consumption of fertilizers in New Jersey in 1898 "was greater than in any previous year in which the statistics were gathered, being nearly 4,000 tons more than in 1896 and nearly double the amount reported in 1889." The number of distinct brands was greater than in any previous year except 1896. The 321 brands of which analyses are reported were the product of 90 manufacturers. The fertilizers examined furnished on the average the total amount of plant food guaranteed, but in only 69 per cent of them was it distributed in the proportion stated.

The average composition, estimated value, and selling price of all brands of complete fertilizers examined during 1899 were as follows: Total nitrogen, 2.41; total phosphoric acid, 10.58 (soluble phosphoric acid, 8.27; insoluble phosphoric acid, 2.31); potash, 5.67; station valuation, $19.95; selling price, $27.75; actual difference, $7.80; percentage difference, 39.1. Comparison of these figures with similar data for previous years (E. S. R., 10, p. 1032) shows "that notwithstanding the tendency toward furnishing less nitrogen and more phosphoric acid and potash the composition of the average fertilizer has been remarkably uniform for the past 8 years."

The average cost per pound of nitrogen in the samples (8) of nitrate of soda examined was 12.16 cts.; sulphate of ammonia (1 sample), 14.29 cts.; dried blood (5 samples), 12.91 cts.; ground fish (16 samples), 13.31 cts.; tankage (8 samples)—fine, 15.51 cts., coarse, 11.15 cts. The average cost per pound of soluble phosphoric acid in plain superphosphates (16 samples) was 3.65 cts. The cost of phosphoric acid in tankage (8 samples) was—fine, 4.46 cts., coarse, 2.23 cts. The average cost per pound of potash in muriate of potash (13 samples) was 4.03 cts.; in kainit (3 samples), 4.48 cts.; and in sulphate (1 sample), 5.27 cts.

Rules for the construction of manure pits (*Deut Landw. Presse, 27 (1900), No. 4, p. 33*).—The rules formulated by a commission of the agricultural council of Pomerania.

Poultry manure (*Queensland Agr. Jour., 6 (1900), No. 1, pp. 23–25*).—A brief summary of information on the value of this material as a fertilizer.

On nitrate-reducing bacteria, W. Krüger (*Chem. Ztg., 23 (1899), No. 80, pp. 848, 849*).—A brief reference to investigations which indicated that straw furnishes an excellent basis for a culture medium for these organisms.

A contribution to the knowledge of denitrification and the decomposition of animal manures in the soil, K. Rogoyski (*Anzeiger Akad. Wiss. Krakau, 1899, pp. 385–411*).

The decomposition of nitrates in soils in field experiments, W. SCHNEIDEWIND (*Chem. Ztg., 23 (1899), No. 80, pp. 848, 849*).—A brief reference to experiments of the same character as those noted in E. S. R., 11, p. 32. In field experiments with mustard there was a destruction or conversion into insoluble forms of 13.9 lbs. of nitric nitrogen per acre during 5 weeks following the application of 11.13 tons of fresh manure per acre. The loss was still greater when the urine or nitrate was applied in mixture with the manure.

On denitrification, T. PFEIFFER (*Chem. Ztg., 23 (1899), No. 80, p. 849*).—This is mainly a discussion of the views of Schneidewind and Krüger referred to above (p. 830). It is stated that at least three factors are involved in the injurious effects under consideration, viz, (1) direct injury to plant growth by the large amounts of organic matter applied in the manure, (2) the fixation of readily soluble nitrogen due to the increased activity of bacteria, and (3) denitrification proper, and it is claimed that many more experiments are needed to determine which of these is the controlling factor.

The use of nitrate of soda as a chemical fertilizer in agriculture and viticulture (*Ann. Sci. Agron., 1899, I, Nos. 1, pp. 38-160; 2, pp. 161-207; 3, pp. 361-458*).—A series of reports of the results of field experiments in the various departments of France.

Is ammoniacal nitrogen of the same value as nitric nitrogen? G. SMETS (*Belg. Hort. et Agr., 11 (1899), No. 19, pp. 293, 294*).

Disposal of sewage and garbage in foreign countries (*U. S. Spec. Consular Rpts., 17 (1899), pp. 13-221*).—This consists of reports on this subject made at the instance of this Department by consular officers at various places in Europe, Asia, Africa, Canada, Australasia, Mexico, Central and South America, and West Indies.

Formulæ for preparing fertilizers for different crops, F. B. GUTHRIE (*Agr. Gaz. New South Wales, 10 (1899), Nos. 7, pp. 605-610; 9, pp. 919, 920; 10, pp. 1061, 1062; 12, pp. 1275-1281*).

Recent progress in the field of fertilizer industry, VON GRUEBER (*Chem. Ztg., 24 (1900), No. 2, pp. 7-10*).—This reviews briefly the general business situation, advances in the manipulation of fertilizing materials, and improvement in scientific and technical processes (especially methods of analysis) relating to fertilizers.

Commercial fertilizers, H. A. HUSTON (*Purdue Univ. Spec. Bul., Aug., 1899, pp. 8*).—This is a second edition of this bulletin containing additional analyses made since the publication of the first edition in May (E. S. R., 11, p. 438).

Fertilizers, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 159-161*).—This includes analyses of 6 samples of swamp muck and 2 of Thomas slag, with a brief discussion of the fertilizing value of these materials and of South Carolina phosphate.

Analyses of fertilizing materials, H. SNYDER (*Minnesota Sta. Bul. 63, pp. 508-510*).—Analyses are reported of nitrate of soda, dried blood, tankage, sheep manure, soft-coal soot, peat-bog ashes, sawmill ashes, and hard-wood ashes.

Analyses of commercial fertilizers (*South Carolina Sta. Bul. 45, pp. 23*).—This bulletin completes the report of analyses of fertilizers for the season of 1898-99. It contains analyses and valuations of 149 fertilizers, together with notes on valuation, directions for sampling, and regulations governing the sale of commercial fertilizers in South Carolina.

FIELD CROPS.

Field experiments with farm crops, W. SAUNDERS, R. ROBERTSON, S. A. BEDFORD, A. MACKAY, and T. A. SHARPE (*Canada Expt. Farms Rpts. 1898, pp. 16-69, 111-114, 117-118, 151-153, 242-256, 271-299, 328-351, 377-393*).—These experiments consist as heretofore (E. S. R., 10, pp. 835, 836) of variety, cultural, and fertilizer tests with grain, root, and forage crops. The tests are being carried on at the experimental farms in Ontario, the Maritime Provinces, Manitoba, British Columbia, and the Northwest Territories. The results of the variety tests have been previously recorded (E. S. R., 10, p. 1035). The distribution of seed grain by the Central Station at Ottawa and certain branch farms is noted. The cultural experiments consist of early, medium, and late sowings at different stations of oats, barley, spring wheat, peas, turnips, mangels, and flax; distance experiments with corn; early and late harvesting of root crops; rotation tests, etc. The results of these experiments are tabulated in detail, and in some instances averaged for preceding years.

In Manitoba wheat sown after sweet clover gave better results than when sown on wheat stubble, but not as good as when sown on summer fallow. Rolling the ground before sowing the seed increased the yield of both grain and straw. Seeding with the hoe drill gave better results than seeding with a press drill or sowing broadcast. Five pecks of seed wheat per acre proved better than 4 or 6 pk. per acre. Spring-plowed land proved better for wheat than fall plowed. The earliest seeding of wheat gave the best results. Sprinkling either clean or smutted seed wheat with a dilute solution of copper sulphate decreased the percentage of smutted grain in the harvest. Formalin proved superior to Bordeaux mixture or copper sulphate for controlling the smut in both wheat and oats. Samples of smutted seed steeped in formalin even for 5 minutes gave yields almost free from smut.

The clovers have proven specially valuable as a green manure at the Ontario Station. Data are given as to the fall weights of the leaves and stems and of the roots taken to a depth of 9 in. of mammoth red, common red, and alsike clover, when seeded the preceding spring at different rates per acre. In one instance clover was allowed to grow until the following May before the weighings were made. The weight of the green product was nearly doubled by the additional growth. This fact has an important bearing on the time of plowing under clover for green manuring. In one instance clover seed inoculated with Nitragin gave nearly double the weight of leaves, stems, and roots obtained from seed not inoculated. In other instances it considerably increased the growth of clover. Once the results did not seem to be influenced by its use. Clover seeded with grain did not decrease the yield of grain.

Early sowing and late harvesting gave the best results with turnips, mangels, and carrots. With sugar beets late sowing and late harvesting gave the best yields at Ottawa and the Northwest Territories. In the Maritime Provinces, Manitoba, and British Columbia early sown sugar beets gave the best yields. The sugar content of beets grown in British Columbia varied from 10.4 to 16 per cent. Corn in British Columbia gave the best leaf growth and matured better when the rows were 3½ ft. wide or more. In the Northwest Territories the closer the planting in the case of hill culture the better the result, while in row culture the reverse was true. Early sowings of flax have generally given the best results as regards both seed and straw. Soy beans and horse beans have been successfully grown at all the stations. Planting soy beans in drills from 14 in. to 2 ft. apart has given the best results. When oats and peas were mixed, the seeding containing the largest proportion of oats gave the largest yield of grain.

In the fertilizer experiments at the Central Station, fresh barnyard manure has given the best average results on barley, corn, and carrots of all the different fertilizers and combinations tested during a period of 11 years; and rotted barnyard manure on wheat, mangels, turnips, and potatoes. Mineral phosphate has been discarded as a fertilizer. Ten years' experience with this material has shown it to possess no value as a fertilizer. In rotation tests, wheat alternated with roots or corn has given the largest money returns.

Tabulated data are given as to the date of topping; total weight of first, second, and third grade dried leaves; and estimated total weight per acre of dried leaves of 35 varieties of tobacco. "The Kentucky Burley, White Burley, Yellow Pryor, Yellow Mammoth, Connecticut Seed Leaf, and Pennsylvania Seed Leaf are, taking everything into consideration, probably the most profitable varieties to grow. Some of those which yielded heavier than these were too late in maturing to reach the best condition." Other minor crops grown at the different stations are sunflowers, grasses, Japanese millet, spring rye, buckwheat, rape, and mixed fodder crops.

Report of the agriculturist and horticulturist, A. J. McClatchie (*Arizona Sta. Rpt. 1899, pp. 242-259*).—A report is given of cultural experiments at the station with sugar beets, plants for green manuring, wheat, barley, potatoes, garden vegetables, melons, forage crops, and eucalypti; and of the effect of winter irrigation on orchards. The horticultural work is noted elsewhere in this issue.

Sugar beets.—Seeding at different dates, early irrigation, and planting on adobe soil were problems investigated in the testing of sugar beets. The details are reserved for future publication. The summarized results of the season indicate that beets sown January 18 gave better results than when sown February 13 or 26. Kleinwanzlebener gave better yields than Vilmorin even on heavy clay soils. Winter-sown beets were not benefited by early irrigation. "The best time to apply water is when the beets are between 2 and 3 months old." Fairly good results were obtained at the station when beets were sown in September and harvested the following March.

Green manure plants.—Yellow sweet clover, crimson clover, alfalfa, and different varieties of peas were tested. Dates for seeding and plowing under the different crops and yields of green and dry matter per acre are tabulated. Yellow sweet clover and alfalfa were the only plants which gave satisfactory yields. Crimson clover was not a success and it is thought doubtful whether peas can be profitably sown at the station for green manure. The author states that yellow sweet clover is probably the green manure plant best suited to station conditions.

Wheat.—The object of the experiment with wheat was to find varieties for introduction of better milling qualities than those at present grown. Seventeen varieties were grown, 8 of which were new to the region. The central portion of each plat was dressed with horse manure. Different methods of irrigation were tested. Data for the experiments are tabulated. Sonora, the variety usually grown at the station, proved the earliest of all the varieties tested. It was surpassed in yield, however, by Ruby and Feldspar, varieties from New Mexico. Seven varieties proved superior to Sonora in milling qualities. Of these Rorsa di afulia, Ruby, and Jones Winter Fife are considered the most promising as regards productiveness and earliness. The average increased yield of all varieties due to manuring was 18 per cent. Furrow irrigation gave better results than flooding.

Barley.—Barley was grown for hay and for grain. One bearded, one beardless, and one hulless and beardless variety were tested. The hulless variety lodged the least and gave the largest yield of grain per acre. Both the hulless and the beardless varieties matured earlier than the bearded variety and made hay of excellent quality, though the yield was not quite so heavy as with the bearded variety.

Potatoes.—The period between winter frosts and the intense heat of summer is so short in Arizona that only early varieties of potatoes can be grown. Data for tests of 12 early varieties are tabulated. Early Rose, the variety usually grown at the station, planted February 15, gave the largest total yield. Some of the plats were fertilized with barnyard manure, some with ashes alone, and some with ashes and manure combined. The data are tabulated, but the results are inconclusive.

Mention is made of the forage plants being grown at the station.

Experiments with corn, J. S. NEWMAN (*South Carolina Sta. Bul. 41, pp. 6*).—Tabulated results, with comments, are given on experiments with corn, involving planting, tillage, distance, and fertilizer tests; comparison of kernels from different parts of the ear for seed; and on excessive manuring, tillage, and irrigation.

Corn planted on the level without cultivation, except the cutting out of grass and weeds with the hoe, gave practically as good yields as corn planted in furrows and cultivated shallow the first time, afterwards deep. In general the yield of corn increased with the number of stalks per acre. The largest total yield was obtained when single kernels were planted in rows 4 ft. apart and 1 ft. distant in the row. The alluvial soils on which these experiments were carried out were not benefited by the addition of either commercial fertilizers or compost. Excessive irrigation produced a succulent growth of corn and decreased the total yield.

Cotton, J. S. NEWMAN (*South Carolina Sta. Bul. 46, pp. 4*).—The time of application, kind, quantity, and combination of fertilizers most suited for the production of lint cotton on sandy upland soil with red clay subsoil was investigated. In one group of experiments, fertilizers applied April 30 gave better results than when applied February 17, but on a somewhat lighter soil the early application usually gave better results. The data as to the combinations and amounts of different fertilizers applied and yields obtained are tabulated, but the results are more or less conflicting and no conclusions are drawn.

The effect of nitrogenous fertilizers on the yield and composition of certain grasses, grains, and legumes, W. O. ATWATER and C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1898, pp. 113-203*).—Experiments along these lines have been in progress at the station since 1888 (E. S. R., 9, p. 746). The object of the investigations has been to determine the effect on the yield and composition of certain farm crops when fertilized with different kinds and quantities of nitrogenous fertilizers used with uniform quantities of potash and phosphoric acid. The relative economy of using the different nitrogenous fertilizers has also been studied.

The plan of the experiment provides for "special nitrogen experiments" in which 320 lbs. of dissolved boneblack containing 53 lbs. of phosphoric acid, 160 lbs. of muriate of potash containing 82 lbs. of potash, and different quantities of either nitrate of soda, sulphate of ammonia, or dried blood, sufficient in each instance to furnish 25, 50, or 75 lbs. of nitrogen per acre, were used; and for "soil test experiments" in which fertilizers containing 53 lbs. of phosphoric acid, 25 lbs. of nitrogen, and 82 lbs. of potash were applied on different test plats, singly and in combinations of two and three. The detailed data for the different experiments since the beginning of the work in 1888 are tabulated and all the results, including those obtained in 1898, are considered together.

The experiments with mixed grasses for hay (E. S. R., 5, p. 578) show a regular increase in yield with each increase in the amount of nitrogen applied in connection with the mineral fertilizers, though the yield when 75 lbs. of nitrogen was applied was but little greater than when only 50 lbs. was used. Mineral fertilizers increased the yield of the mixed grasses but slightly and were used at a financial loss. The net profit resulting from the use of 25 lbs. of nitrate nitrogen in connection with mixed mineral fertilizers was at the rate of $3.05 per acre; when 50 lbs. of nitrate nitrogen was used with mineral fertilizers, the profits averaged $6.61 per acre; and when 75 lbs. of nitrogen was used with the mineral fertilizers, $4.47 per acre. The profits were slightly less when sulphate of ammonia was used as a source of nitrogen, though the proportionate profits with the different amounts applied were about the same.

The protein content of the hay was markedly affected by the nitrogenous fertilizers. It increased quite uniformly with each increase in the quantity of nitrogen applied. On the plats where mineral fertilizers alone were used, the protein content of the crop averaged 7.83 per cent. The protein increased to 7.95 per cent when 25 lbs. of nitrate nitrogen was added to the mineral fertilizers, to 8.46 per cent when 50 lbs. was added, and to 9.42 per cent when 75 lbs. was added; and the effects were practically the same when the source of the nitrogen was sulphate of ammonia.

"The increase in the total yield of protein was relatively much larger than the increase in the total yield of dry matter; for if the yields from the plats upon which the mineral fertilizers only were used be taken as a basis, the relative yields from the plats upon which 25, 50, and 75 lbs. of nitrogen was used in addition to the minerals, were respectively as follows: Of dry matter, 137, 177, and 188 per cent; of protein, 127, 188, and 222 per cent."

With corn, the yield of both grain and stover regularly increased with the amount of nitrogen in the fertilizers applied until the nitrogen in the latter reached 50 lbs. per acre. Increasing the nitrogen content of the fertilizers to 75 lbs. per acre increased the yield but slightly. The protein content of the grain, on the other hand, gradually increased with each increase in the amount of nitrogen applied.

"Thus in the experiments with nitrate of soda as a source of nitrogen, the proportions of protein were as follows: In the corn from the mineral plats, 10.13 per cent; from the plats with 25 lbs. of nitrogen, 10.80 per cent; from the plats with 50 lbs. of nitrogen, 11.50 per cent; from the plats with 75 lbs. of nitrogen, 12.07 per cent."

When sulphate of ammonia was used as a source of nitrogen, the protein increased with each additional amount of nitrogen applied, but the percentages were not so high as when the nitrate of soda was used. An increase in percentage of protein did not follow an increase in the amount of dried blood used, but as only 2 experiments with dried blood were made, the results are not considered conclusive. The most economical results obtained with the different fertilizers on corn were obtained from the plats fertilized with nitrate of soda in connection with the mineral fertilizers at the rate of 160 lbs. (25 lbs. of nitrogen) per acre.

One soil test and 2 special nitrogen experiments were made with oats. The yields and composition of the oats grown on the different plats are tabulated and discussed. Unfavorable seasons and soil conditions make it practicable to draw only general conclusions. "In all the experiments in which nitrogen was used, the yield was markedly increased. In general, the results are similar to those obtained with mixed grasses and corn. The effect of the nitrogen on the composition of the crop, especially of the seed, was quite marked. This was most noticeable on the plats to which nitrate of soda was applied."

Plats of timothy, orchard grass, tall meadow fescue grass, tall red top, tall meadow oat grass, and brome grass were grown. The comparatively small size of the plats made it impracticable to estimate the yield per acre of the different plats, but the composition of each of the different species as influenced by increasing amounts of nitrogen was studied. These data are tabulated. The effect of the nitrogen in increasing the protein of the crop was more noticeable in this instance than with any of the preceding crops mentioned. The average protein content of the grass grown without fertilizers was 7.62 per cent; with mineral fertilizers alone, 7.39 per cent; with mineral fertilizers plus 25 lbs. of nitrogen, 9.72 per cent; and with mineral fertilizers plus 75 lbs. of nitrogen, 12.49 per cent.

The report upon experiments with legumes is confined to cowpeas and soy bean. Mineral manures greatly increased the yields of these crops, but there was no increase whatever in the fodder yield of cowpeas when nitrogen was added to the mineral fertilizers. The yield of soy-bean seed was slightly increased by the addition of nitrogen, but not sufficiently to make its use at all economical. Little relationship seemed to exist between the quantity of nitrogenous fertilizers applied and the dry matter and protein content of the resulting crops of either cowpeas or soy beans, though a slight increase in protein content followed the application of the larger amounts of nitrogen.

The comparative effects of increasing the amounts of nitrogenous fertilizers on the yield of dry matter and protein of grasses and corn as compared with the yields of cowpeas and soy beans by use of similar amounts of the same fertilizers are shown in the following table:

Yields of dry matter and protein in different crops similarly fertilized.

Fertilizers.	Grasses.		Corn, grain.		Cowpeas, green plant.		Soy beans, seeds.	
	Dry matter.	Protein.	Dry matter.	Protein.	Dry matter.	Protein.	Dry matter.	Protein.
	Per ct	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Minerals only	100	100	100	100	100	100	100	100
Minerals + nitrogen 25 lbs	137	127	135	143	104	100	102	105
Minerals + nitrogen 50 lbs	177	188	165	181	100	101	115	120
Minerals + nitrogen 75 lbs	188	222	168	200	98	100	117	123

The practical results of the work are thought to teach the necessity of adapting the fertilizers to the crops grown. The true grasses, like timothy and redtop, are most benefited as regards yield and composition of crop by the application of immediately available fertilizers like nitrate of soda and sulphate of ammonia during the early stages of growth. Slow-acting nitrogenous fertilizers may be used on corn. The yield of legumes is considerably increased by the application of mineral fertilizers, but is only slightly affected by the use of nitrogenous manures.

Fertilizer experiments with mangel-wurzels, Swedish turnips, and grass (*Rpt. Agr. Expts. Cornwall County Council, 1898, pp. 3–26, 43, 44*).—A large number of field experiments with fertilizers are reported. As a result of 991 experiments, extending over a period of 2 seasons, the following fertilizer formula is recommended for mangel-wurzels: 2 cwt. of sulphate of ammonia, 3 to 6 cwt. of superphosphate, and 2 cwt. of kainit per acre drilled with the seed, and 4 cwt. of nitrate of soda, 4 cwt. of salt, and 2 cwt. of kainit per acre broadcast, the salt and kainit being applied at seed time, 1 cwt. of nitrate of soda per acre just after the roots are hoed, and the remaining 3 cwt. of nitrate of soda in 3 equal quantities at intervals of about 3 weeks.

As a result of 2,047 experiments, extending over a period of 3 seasons, the following fertilizer formula is recommended for Swedish turnips: 6 cwt. of superphosphate, 2 cwt. of kainit, and if there is a probable deficiency of nitrogen in the soil, ½ cwt. of nitrate of soda per acre drilled in with the seed. The results of fertilizer tests on grass are tabulated, but no formula is recommended and no conclusions are drawn.

A preliminary report is made of experiments with fertilizers to determine those best adapted for permanent pasture land. The results of the test are tabulated, but in this case also no conclusions are drawn. An application of 10 cwt. of basic slag and 1 cwt. of muriate of potash per acre gave the best results. giving a yield of 9,333 lbs. of hay as against 4,442 lbs. from a check plat unmanured.

The influence of commercial fertilizers on the quality of the Irish potato, R. J. DAVIDSON (*Virginia Sta. Bul. 92, pp. 97-108*).—A study extending over a period of 3 years was made to determine the effect of different amounts and combinations of commercial fertilizers upon the quality of Irish potatoes, and also to observe in what manner the amount of plant food taken up by potatoes is affected by fertilizers.

Three varieties of potatoes were used: Charles Downing, Early Ohio, and Sunrise, and 23 plats given to the culture of each. The fertilizers used were nitrate of soda, acid phosphate, and muriate and sulphate of potash. Four plats in each series were left unfertilized. The yields and composition of the potatoes grown on each plat are shown in tabular form and the results discussed.

No difference was observable in the effect of the fertilizers on the different varieties of potatoes. The highest percentage of dry matter was found in the potatoes grown on the unfertilized plats, an average for these plats of 22 per cent. The lowest content of dry matter found in any of the samples was 19.91 per cent. These potatoes were grown on plats excessively fertilized with all three essential elements. Between these two extremes considerable irregular variation occurred. The average content of dry matter of potatoes grown on the plats fertilized with muriate of potash was 20.45 per cent and on the plats fertilized with sulphate of potash 21.20 per cent, a slight advantage in favor of potatoes grown with the sulphate. The average starch content of the potatoes grown on the unfertilized plats was 68.37 per cent, and on the fertilized plats 69.54 per cent. On the plats fertilized with the muriate of potash the starch content of the potatoes was 69.99 per cent and on the sulphate plats 69.35 per cent. But little difference was observable in the starch content of potatoes grown on different plats, whether one or more fertilizers were used or whether small or large amounts were applied.

> "It can therefore safely be said, in summing up the evidence as given of these results, that fertilizers have very little effect on the starch content. The starch does not seem to be affected much by either the large or small application, nor does it make very much difference whether we use muriate or sulphate of potash."

The crude ash content of the potatoes seemed to be but little affected by the fertilizers. It was slightly increased when muriate of potash was used, due to an increased absorption of chlorin by the plant. The increase in chlorin was found to vary directly with the amount of muriate of potash used. The conclusions of the author may be summed up as follows:

Commercial fertilizers tend to diminish the content of dry matter in potatoes and to slightly increase the starch and ash content. "Neither the kind nor amount of fertilizers has any appreciable effect on the percentage of nitrogen, phosphoric acid, and potash contained in the potatoes. The percentage of chlorin is considerably increased when muriate of potash is used, and the more muriate used the higher the percentage of chlorin. Potatoes grown with muriate of potash contain less dry matter but slightly more starch than those grown with sulphate of potash."

Experiments on the cultivation of different varieties of tobacco on the Signakski and Sochinski Experimental Tobacco Plantation (*Selsk. Khoz. i. Lyesov., 193 (1899), June, pp. 481–558*).—Variety tests and culture experiments were made to determine the influence on yield and quality of tobacco, of thickness of planting, and of the number of leaves left on the plant when transplanted. The varieties "Platana" and "Samsoon," both of Asia Minor, and "Dubec," of Macedonia, were found best suited to the soils of the region. Results of the culture experiments tend to show that within certain limits the yield of tobacco increases with the thickness of planting and with the larger number of leaves left on the seedlings when transplanted. The thickness of planting has also an important influence on the quality of the tobacco. The greater the distance the plants are set apart, the more inferior the quality; or, stating it in another way, the quality of tobacco improves up to a certain limit with the increased thickness of planting.—P. FIREMAN.

Experiments in the culture of the sugar beet in Nebraska, H. H. NICHOLSON and T. L. LYON (*Nebraska Sta. Bul. 60, pp. 34, figs. 6, dgm. 1*).—This bulletin records the results of cultural and fertilizer experiments and of variety and seed tests with sugar beets during the season of 1898.

The experiments were conducted on a 5-acre plat of typical sugar-beet soil at Ames, in the Platte River Valley. In addition to this experimental plat the station had the privilege of using for purposes of investigation 300 acres of sugar beets, including 30 different varieties, planted by the Standard Cattle Company of the same place. Mechanical and chemical analyses are given of the gumbo and sandy loam soils of this farm. Field notes on the growth of beets on plats differently treated are given, and the results of the different experiments shown in tabular form. The results of the season's work led to the following conclusions:

> "No advantage was derived this year from the use of "large seed" or "heavy seed."
>
> "The most satisfactory method of planting was in rows 18 in. apart, and thinning out the beets to 8 in. in the row, as compared with rows 30 in. apart with beets 4 in. apart, and also as compared with hills 18 by 8 in. apart.
>
> "Shallow cultivation and hoeing are preferable to deep cultivation and hoeing.
>
> "A slightly increased yield of beets was produced by the use of commercial fertilizers, but no improvement in sugar content and purity.
>
> "A comparison of a light soil with a heavy one showed that beets on the former matured more rapidly, but those on the heavy soil attained the higher sugar content and purity."

The labor-saving devices employed in the rapid analysis of between 6,000 and 7,000 specimens of sugar beets, used as mothers for the production of seed, are described in considerable detail, and results given of germination tests of 15 samples of imported sugar-beet seed and of examinations of the same with reference to purity.

Report of the results obtained on the experimental fields at Dodd's Reformatory, 1898, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Rpt. Expt. Fields Dodd's Reform.* [*Barbados*], *1898, pp. 39*).—Part 1 of this report shows the amount and composition of rainfall during the years 1896–1898, and part 2 includes reports of experiments with commercial fertilizers on sugar cane. The size of the plats, nature of the soil, and similar data have been previously noted (E. S. R., 10, p. 40). Results secured in 1898, as shown by tables, are commented upon and summarized. The use of nitrogen, either in the form of sulphate of ammonia, nitrate of soda, or dried blood, with mineral fertilizers resulted in an increase in tonnage of cane, volume of juice, available sugar, and profits. An application of 60 lbs. of nitrogen per acre in the form of sulphate of ammonia led to an increase of sugar and profits, but when the amount was increased to 80 lbs. per acre. a loss followed. Both sulphate of ammonia and nitrate of soda proved superior to dried blood as sources of nitrogen. The use of phosphate fertilizers in addition to nitrogen and potash resulted regularly in a decrease of sugar and profits, except in one instance where superphosphate was used at the rate of 40 lbs. per acre. Increasing the amount of phosphate increased the loss in each instance. The use of potash in connection with nitrogen and phosphoric acid regularly increased the yield of cane, juice, sugar, and profits. The increase of profits was very small, on the average. and was greatest in the case of the plat which received 60 lbs. of potash per acre applied in January.

Applying all the potash in January gave slightly better results than applying part in January and part in June.

A summary of all the experiments shows that applications of 30 tons of barnyard manure were unprofitable. The use of mineral fertilizers alone did not increase the yield of sugar. "Nitrogen was the manurial constituent which chiefly governed the return of sugar and profit. When applied in addition to mineral fertilizers it gave the best return when applied to the amount of 60 lbs. of nitrogen per acre in either of the active forms of sulphate of ammonia or nitrate of soda."

A large number of varieties, mainly seedlings, of sugar cane were tested. Nineteen of the varieties grown yielded over 7,000 lbs. of available sugar per acre, the yields of cane varying from 29 to 48 tons per acre, and the juice containing from 14.45 to 19.27 per cent of sucrose. Some of the best varieties were among the selected seedlings, and of these the best results were given by Burk and Demerara seedlings.

Improvement of cane by selection on the basis of analysis has been undertaken but no results have as yet been reached.

Report on the results obtained on the experimental fields at Dodd's Reformatory, 1899, J. P. D'ALBUQUERQUE and J. R. BOVELL (*Rpt. Expt. Fields Dodd's Reform. [Barbados], 1899, pp. 38*).—This report is similar in character to the report for 1898 (see above). The experiments there reported were continued in 1899 under entirely similar conditions. Hurricanes and drought seriously interfered with the results of the year. "This was especially noticeable with the nitrogenous applications, neither sulphate of ammonia nor nitrate of soda being applied with profit. Dried blood, however, gave an increase in sugar and profit. The addition of superphospate of lime to fertilizers containing nitrogen and potash resulted in every case in loss. In one instance a plat fertilized with 100 lbs. of basic slag gave an increased yield in available sugar and was used at a fair profit." The application of sulphate of potash was in every case followed by favorable results, and these results were most favorable in the case of the plat receiving sulphate of potash at the rate of 40 lbs. of potash per acre, applied in January.

In the variety tests selected seedlings gave better results than older varieties. Among these Demerara seedlings and Barbados seedlings again stand at the head.

Wheat and oats, rye and barley, R. J. REDDING (*Georgia Sta. Bul. 44, pp. 19*).—Popular directions for the culture and manuring of wheat and oats for grain and for the culture of barley and rye for pasture. Part of the data here recorded has been previously noted (E. S. R., 3, p. 387).

Results at the station seem to favor the use of fertilizers for wheat and oats which contain relatively large amounts of nitrogen. Nitrate of soda is especially recommended as a top-dressing for oats. Tests of a number of varieties of oats grown at the station in different years are recorded in tabular form. Texas Rust Proof is considered the most reliable variety to grow in the South. Appler is also a good variety. Winter Turf oats have not proven desirable at the station. Fertilizer formulas are suggested for both oats and wheat.

Memoranda of the origin, plan, and results of the field and other experiments conducted on the farm and in the laboratory of Sir John Bennett Lawes at Rothamsted, England, J. H. GILBERT (*Report to the Lawes Agr. Trust Committee, 1899, pp. 113, figs. 2, dgms. 7*).—This is a report on the work of the Rothamsted Experiment Station containing summarized results of its work from organization to the present time. The year 1899 was the fifty-sixth year of the experiments. The work carried on there has already been fully described in Bulletin 22 of this Office (E. S. R., 7, pp. 372, 380, 385, 387, 390, 398, 415).

Report of the farm overseer, F. GILLANDERS (*New Zealand Dept. Agr. Rpt. 1899, pp. 161-168, 173-197*).—A large number of variety and fertilizer tests with barley, wheat, potatoes, turnips, mangel-wurzels, carrots, sugar beets, kohl-rabi, peas, and cabbage are reported.

Experiments with crops, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 6 (1897), pp. 7-116, dgms. 5*).—Results are given of rotation and fertilizer experiments with barley, oats, potatoes, and various root crops grown in the counties of Durham, Cumberland, and Northumberland in England. Fertilizer experiments on pasture and old hay fields are also recorded.

Culture of hardy alfalfa, G. D'UTRA (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 8, pp. 419-463*).—Data on the yield and chemical composition of *Medicago media* and *M. sativa* harvested before, during, and after bloom.

Cotton culture in the German colonies, E. HENRICI (*Tropenpflanzer, 3 (1899), No. 11, pp. 535-548*).

Manuring meadows (*Deut. Landw. Presse, 26 (1899), No. 95, p. 1071*).—Mineral fertilizers were used on low meadows without effect. Nitrogenous fertilizers (nitrate of soda) greatly increased the yields.

Commercial fertilizers for natural and artificial meadows, E. ZACHAREWICZ (*Prog. Agr. et Vit. (Éd. L'Est), 21 (1900), No. 5, pp. 155-160*).—Complete commercial fertilizers were compared with liberal amounts of barnyard and liquid manures for natural and artificial meadows. Both the heaviest yields and the greatest financial profits were obtained on the plats fertilized with commercial fertilizers.

The opuntias, J. W. TOUMEY (*Arizona Sta. Rpt. 1899, pp. 240*).—Mention is made of the work of selection and hybridization of cactus fruits which is now being carried out in the university garden for the purpose of increasing their economic value as food plants.

The ground nut (Arachis hypogæa), C. BENSON (*Dept. Land Records and Agr., Madras, Vol. II, Bul. 37, pp. 136-144*).—Statistics on the decreasing production of peanuts in some of the more important peanut-growing districts of India, with a discussion of the probable cause (soil deterioration) and analyses of 6 peanut soils.

Saltbushes, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1899, p. 207*).—A brief report is given of experiments with *Atriplex nummularia*, *A. halimoides*, and *A. leptocarpa*. All these plants grew well, were quite resistant to drought, and were freely eaten by stock.

A monograph on the sugar beet, W. HERZOG (*Monographie der Zuckerrübe. Hamburg: Leopold Voss, 1899, pp. VII+170*).

The sugar beet in Italy, C. MANCINI (*La barbabietola da zucchero in Italia. Rome: E. Loescher & Co., 1899, pp. 120*).

Sugar beets, C. D. SMITH and R. C. KEDZIE (*Michigan Sta. Spec. Bul. 10, pp. 4*).—Cultural directions for the use of sugar beet growers.

Manuring sugar beets with potash on heavy soils, C. Fruwirth (*Württemburg. Wchnbl. Landw., 1899, No. 52, pp. 821-823*).

A report of progress in beet and beet seed culture (*Bl. Zuckerrübenbau, 7 (1900), No. 1, pp. 8-12*).—Experiments with manures and fertilizers on sugar beets.

The question of woody beets, A. Krüsemann (*Deut. Landw. Presse, 26 (1899), No. 95, p. 1069*).—To prevent the frequent occurrence of sugar beets going prematurely to seed and thus forming woody roots, the author recommends that spring sowings be delayed, especially when the spring is cold and backward, that the plants be well and frequently fertilized with nitrate of soda during the early stages of growth, and that frequent cultivation be practiced.

The distribution of sugar in beets as related to the paying for beets according to sugar content, A. M. (*Bl. Zuckerrübenbau, 6 (1899), No. 18, pp. 273-283, figs. 11*).

Seedling sugar canes, crop 1899, Carmody (*Bul. Roy. Bot. Gard. Trinidad, 1898, No. 21, pp. 221-223*).—The composition of 39 best canes grown by the botanical department in 1899 is reported. Brief statements are also made concerning the crop.

Improvement of sugar cane by chemical selection (*Sugar, 12 (1900), No. 3, p. 45*).

The cultivation and improvement of tobacco in Spain, J. Rallo y Campuzano (*Tratado del cultivo y beneficio del tabaco en la Peninsula. Madrid: J. de Castro, 1899, pp. 87*).

Culture of tobacco in Mexico (*Tabac, 19 (1899), No. 351, pp. 3, 4; 20 (1900), No. 355, p. 3*).—Brief survey of the possibilities of tobacco culture in Mexico.

Intensive culture of wheat, Herbert (*Culture intensive du blé. Paris: J. B. Baillière & Sons, 1899, pp. 40*).

Studies and investigations on the grain of wheat, E. Frichot (*Études et recherches sur le grain de blé. Paris: J. B. Baillière & Sons, 1899, pp. 237, figs. 25*).

Rust resistant wheats (*Agr. Jour. Cape Good Hope, 15 (1899), No. 13, pp. 837-839*).—Methods of securing rust resistant wheats by selection are noted.

HORTICULTURE.

Tomatoes: Composition and food value; loss of nutrients in canning, H. Snyder (*Minnesota Sta. Bul. 63, pp. 513-517, fig. 1*).—Analyses were made of 3 sorts of tomatoes, with the following results:

Composition of tomatoes.

	Variety.		
	Acme.	Livingston.	Dwarf Aristocrat.
	Per cent.	*Per cent.*	*Per cent.*
Sucrose (cane sugar)	1.60	1.62	1.73
Dextrose (glucose)	1.12	1.12	1.03
Levulose (fruit sugar)	1.13	1.12	1.03
Protein	.50	.50	.44
Amids	.36	.40	.36
Fat	.05		
Malic acid	.37	.47	.41
Ash	.69	.56	.54
Insoluble in acid	.32	.34	.37
Undetermined	.25	.11	.16
Water	93.61	93.76	93.93
Total	100	100	100
Total solids	6.39	6.24	6.07

Some of the constituents were studied in considerable detail. Thus the author found that the same amount of sugar could not be obtained from the dry residue of the tomato as from the fresh material. This change was attributed to the combined action of heat, organic acids, and ferments present.

> "The destruction of the levulose [of the tomato] by the prolonged drying in the presence of the malic acid explains the discrepancy in the sugar percentage of the tomato as obtained by different analysts, because some have obtained their sugar results from the dried residue, while others have used the fresh material. This chemical change is not necessarily confined to the levulose of the fresh sample. When the tomato is dried, the sucrose undergoes inversion, and the levulose thus formed undergoes the same change as the preexisting levulose. That this is true is indicated from the results [obtained] and by direct experiments. . . . This same change was observed when solutions composed of sucrose, levulose, and malic acid were evaporated and heated in a water oven.
>
> "The fact that the mixed sugars of the tomato suffer such a material change in drying indicates that the sugar in the dried residue of fruits and vegetables may not always be taken as representing the sugar content of the fresh substance. Drying in a vacuum would probably be the only way of avoiding these changes. . . .
>
> "The direct extraction of the dry matter of the tomato gives about 0.5 per cent of ether extract, commonly called fat. If the residue is first extracted with alcohol, a much smaller amount of ether extract is obtained, as will be observed from the following results:

	Per cent.
Direct extraction of residue	0.49
After extraction with alcohol	.05
Ether extract 1, soluble in alcohol	.41

> "From these results it is evident that about 90 per cent of the ether extract of the tomato consists of non-fatty material."

The loss of nutrients by rejecting the juice in canning tomatoes was investigated, a comparative test being made in which cans were prepared with and without juice. As shown by analysis there was a loss of 22 per cent of the total sugar when 3 lbs. of tomatoes was canned without juice.

Report of the horticulturist, W. T. MACOUN (*Canada Expt. Farms Rpts. 1898, pp. 93–110, 111–117, 119–121, pls. 3*).—Historical notes are given on Russian fruits grown at the Central Experimental Farm since 1888, with descriptive notes on a number of varieties of apples, pears, plums, and cherries. Tests are reported of 25 varieties of grapes, 50 of currants, and 25 of strawberries. Descriptions are given of 4 new varieties of gooseberries originated by W. Saunders.

The cover crops sown August 1, 1897 (E. S. R., 10, p. 849), "came through the winter in splendid condition." Contrary to the usual practice, clover sown as cover crop in the orchards was not plowed under, partly because the soil in the orchard is a sandy loam which is easily moved by the wind, and partly to determine whether the trees would suffer in time of drought. Notwithstanding an exceptionally dry summer, neither clover nor orchard seemed affected by drought except in a small part of the Russian orchard.

Descriptive notes are given on a number of seedling apples, pears, and plums. A list is given of those vegetables which have proved best and most satisfactory at the Central Experimental Farm. Tests are reported of 25 varieties of peas and 103 of tomatoes. The 6 wrinkled varieties of tomatoes which gave the best average yields in 3 years are Early Bermuda, Extra Early Jersey, Early Richmond, Money Maker, Democrat, and Conqueror. The 12 smooth varieties which have given the best results in the same time are Brinton Best, Baltimore Prize Taker, Extra Early Advance, Canada Victor, Comrade, Mayflower, Livingston Favorite, Early Ruby, Cardinal, Atlantic Prize, Thorburn Longkeeper, and Matchless.

Brief mention is made of the progress of the work in forestry. The arboretum has been much augmented during the year.

The pruning of young fruit trees, G. H. POWELL (*Delaware Sta. Bul. 45, pp. 16, figs. 7*).—The author discusses the stub or Stringfellow method of root pruning, presents the results of root pruning experiments carried out on heavy clay land and light sandy loam with different sorts of fruits, and gives some general considerations based on the experiments relative to the formation of root systems of newly planted trees.

In 1896, 54 trees each of two-year old Astrachan apple, two-year old Bartlett pear, one-year old Crawford Early peach, and one-year old Abundance plum on Marianna roots, were planted at the experiment station and in duplicate at Seaford.

> "The land at the experiment station is a heavy, well-drained, clay loam, with a stiff subsoil 8 or 10 in. beneath the surface. The land at Seaford is a warm, well-drained sandy loam, with a stiff subsoil 2 ft. below the surface. The Newark soil is frequently frozen from December to March, while at Seaford it is not unusual for it to remain open the entire winter. . . . The roots of one-third of the trees were pruned to a length of 8 to 10 in., another third to a length of 3 in., and on the remaining third the roots were 'cut back just below the collar and just under the first good side roots,' where the root formation allowed of the Stringfellow cut."

Another lot, consisting of 22 trees each of apples, pears, plums, and peaches of the same age and variety as those noted above, were planted on the station ground in the spring of 1898. One-half of the trees of each variety were root pruned within 3 in. of the stem and the other half were pruned to stubs.

The trees in these experiments were photographed before planting, and were "taken up at various times to study their root formation, the last trees being removed in May, 1899." The results, given in condensed notes and tables, are summarized in the following table:

Growth of fruit trees root pruned to different lengths.

Locality.	Total number of trees pruned.	Number of trees lived out of 72 pruned to—			Number of first-class trees out of 72 pruned to—		
		6 to 8 inches.	3 inches.	Stubs.	6 to 8 inches.	3 inches.	Stubs.
1896.							
Station grounds, heavy clay loam	216	63	70	45	59	66	16
Seaford, sandy loam	216	68	72	62	62	69	37
1898.							
Station grounds, heavy clay loam	88	....	37	30	....	16	3

In order to observe the behavior of stub-pruned peach trees under orchard conditions, 20 trees of the Emma variety were planted in the fall of 1896 across a new peach orchard. The land was warm, well-drained, sandy loam. "Sixteen of the trees lived and in the summer of 1899 could not be distinguished from those in the adjoining rows."

The general results of the experiment lead the author to conclude that the "stub-pruning system is not one of universal application. The method is a practice with local merit rather than a system that is founded on sound principles of plant growth." It is "meritorious chiefly from the economic advantage of handling and planting the trees and wherever its value in a given locality is determined by experimental effort, it would seem a wise policy to adopt it." Long-rooted trees have not behaved as well as those with roots of medium length and it is advised that "Delaware orchardists should prune the roots of fruit trees to a length of 3 to 5 in. at transplanting. Shorter roots present no emphatic advantages, the longer roots are useless and expensive to set in the ground. The ends of broken roots should be removed and the fibrous roots protected from unnecessary exposure."

The author found a wide variation in the development of root systems on different sorts of fruit trees, which suggested the "impracticability of formulating a method of root treatment applicable to all fruit trees." Stub-pruned trees either on light sand or heavy clay failed to develop roots which took a more downward course than the roots of trees otherwise pruned.

"New roots arise from the ends of pruned roots, from fibrous roots, from adventitious buds at the base of the tree, and sometimes from the sides of the larger roots. They arise most easily from the smallest roots. Shortening the roots induces a development of adventitious roots which may compensate the tree for the loss of its smaller feeders. A long root is useful to a transplanted tree mainly to anchor it in the soil while the new roots are forming. Fibrous roots may be of importance to a transplanted tree in that the earliest feeders are developed from them. The vitality of the fibrous roots is not destroyed where trees are carefully handled.

"The direction which the new root system assumes is governed by the character of the soil, by the distribution of plant food and moisture in it, and by the natural habit of the tree. The roots seek the strata of most congenial moisture and accessible plant food.

"Stub-pruned trees are at a disadvantage on heavy soils, on soils that freeze deeply throughout the winter, in a dry fall or spring, or in soils that are slow in warming.

"Stub-pruned trees, with branches shortened to correspond, frequently develop a one-sided root system and an ill-formed top."

Lelong's nurse root process (*Pacific Rural Press; abs. in Montana Fruit Grower, 9 (1899), No. 22, p. 2*).—Lelong's method of growing trees from branches, as given by himself, is as follows: Remove the dirt from the sides of the mother tree until a root the size of a pencil or larger is found. Taper the root to a wedge-shape and graft it obliquely on the branch about 3 in. from the base end. The branch should be of the same species as the standing mother tree. Cover both root and limb with sand and bank the sand around the grafted branch a foot above the ground. The sand should be kept moist by watering 3 times daily. Three or four branches can be nursed by the same mother tree. Under this treatment the base end of the branch calluses and throws out roots while being nourished by the root of the foster mother tree. The following season the branch may be transplanted "a healthy and vigorous tree" and another branch propagated on the same root. This process can be repeated several times. Limbs of a Washington navel orange tree 2 ft. long have been thus grown on roots and have produced "within a few months growth equal to 3 or 4 years with the ordinary method." The process has been applied to 4,000 trees now in Mr. Lelong's nursery and 200,000 specimens of navel orange nursery stock will be treated in the same manner the coming season.

Effect of winter irrigation of orchards, A. J. McClatchie (*Arizona Sta. Rpt. 1899, pp. 257–259*).—Arizona orchardists consider it advisable to irrigate at least once each month from March to September. In order to ascertain how much of this summer irrigation might be rendered unnecessary by the application of an abundance of water during the winter when water for irrigation is most plentiful, an isolated peach and apricot orchard was irrigated 8 times from December to the last of March, after which water was withheld until the end of June. The orchard was cultivated 3 times during the following 3 months. The water content and degree of saturation of the soil were determined in April, May, and June for each foot of soil from the surface down to ground water, a depth of 34 ft. The data obtained, together with notes on the character of each foot of soil, are given in tabular form. The results show that the irrigation water had penetrated to a depth of at least 24 ft.

> "At the time of taking the second set of samples, excepting in the surface mulch, the percentage of water had not decreased much in the upper 4 ft. The amount that had passed through the surface of the soil and through the trees having been about replaced by capillary attraction upward. As a whole, however, the water in the soil had settled. At the time of taking the third set, though the surface soil had become quite dry, there was still an abundance of water within reach of the roots, the amount still available being equivalent to a rainfall of about 25 in."

Trees cultivated under these conditions produced a healthy growth and were well laden with fruit. The apricots made an average growth of 4 ft. per tree and the peaches and apricots that had ripened were considerably larger than usual.

An examination was made of soil in an orchard which had not been irrigated during the winter, but which had received 3 irrigations in April. Below the fourth foot the soil was practically air dry. "In a field which had not been irrigated for 3 years the average water content in the upper 21 ft. of solid clay was but 9.8 per cent during the same month."

Examination of the soil showed an abundance of orchard-tree roots to a depth of 14 to 16 ft., and one peach root was followed into the twentieth foot.

The results of the season's experiments are considered as emphasizing the importance of winter irrigation. "This applies not only to orchard trees but to alfalfa or any other deep-rooted crop."

Root killing of apple trees, N. E. HANSEN (*South Dakota Sta. Bul. 65, pp. 32, pls. 5*).—At the South Dakota Station "apple root-grafts root kill every winter unless deeply covered." During the winter of 1898–99, practically all nursery stock at the station root killed, notwithstanding much of it was heavily banked. The stock included Russian and native seedlings of *Pyrus malus*, Siberian and French crabs, and wild crab from Iowa. The scion roots of all the cultivated apples, including Hibernal, Anisim, Repka Malenka, and Recumbent, also winterkilled. A study of the wood of all cultivated varieties showed that the Hibernal type, as represented by Hibernal and Recumbent, was the hardiest of the whole list of native cultivated apple trees. Tables show the number and variety of apples root killed during the 2 winters, 1896–97 and 1898–99.

There was one exception to the general destruction of seedling roots during the winter of 1898–99. Russian seedlings of *Pyrus baccata* came through the winter in perfect condition. The habitat of this apple is discussed and botanical descriptions, taken from Regel's "Russian Dendrology," given of 12 varieties of *Pyrus baccata* and of 10 varieties of large fruited Siberian crab, *P. prunifolia*. In the author's opinion, the dwarfing tendency of *P. baccata* will probably make its use as a stock of little value in commercial orchards, except in sections where root killing is a source of constant trouble. This dwarfing tendency may, however, prove advantageous on some of the rich soils of the Northwest where apple trees are "prone to form wood instead of bearing fruit." In the neighborhood of the stations and for similar climates the author believes *P. baccata* will prove especially valuable as a hardy stock in test winters.

The early experiments of orchardists in Wisconsin, Iowa, and Minnesota are reviewed. The data show that in the Northwest "the cultivated apple makes a poor union, as a rule, in top grafting upon Siberian crab. In most cases the top outgrows the stock." Top grafting of many varieties on Siberian crabs tends to earlier bearing and shorter life. "Piece-root grafting of Siberian crab seedling roots has been tried quite extensively and the general experience is unfavorable."

The station tested in a limited way the value of growing stocks from hardy varieties of cultivated apples. Seed was selected from Iowa, Minnesota, and South Dakota and planted in the spring of 1897. None of the stock lived through the winter of 1898–99.

The relative merits of bud and piece-root grafting are considered. Piece-root grafts have given the better results in the Northwest because of the opportunity of the deeply placed scion to form its own roots, but even these roots are not hardy against test winters.

"From the evidence at hand it appears that no piece-root grafting will avail. No roots from the scions should be permitted. Stocks for a fair test should be handled much like the Mahaleb or Mazzard stocks for the cherry in Eastern nurseries, setting stocks in nursery first and afterwards when established budding the cultivated apples upon them."

As an aid to the protection of nursery stock the author strongly advises watering trees in the fall before the ground freezes and then applying a heavy mulch.

The keeping qualities of winter apples, P. YOUNGERS, JR. (*Colorado State Bd. Hort. Rpt. 1898, pp. 39, 40*).—Thirty-four varieties of winter apples were gathered in the fall of 1897, mostly in October, and placed in cold storage at a uniform temperature of 36° F. Previous to barreling, each apple was wrapped first in a sheet of waxed paper, using 9 by 12 in. sheets for small apples and 12 by 12 in. sheets for large ones, then in common newspaper. The apples were examined once each month from June to November of the following season. The keeping qualities of the different varieties were marked on a scale of 10 at each examination. The data are tabulated. When the apples were first examined, June 15, the varieties Ben Davis, Winesap, Genet, White Winter Pearmain, Limbertwig, Allen Choice, Willow Twig, Sweet Russet, Little Red Romanite, and Lansingburg were in perfect condition. Four and one half months later, or November 1, when all the apples were removed from cold storage, all these varieties were still in perfect condition, excepting White Winter Pearmain, Sweet Russet, and Allen Choice.

"At the time of the second and third markings, the Jonathan and Grimes Golden Pippin had gained in the comparative scale, coming out of storage in very good condition with flavor fully retained; while the Minkler had lost flavor and begun to decay. The English Golden Russet shriveled and lost on scale. The Roman Stem became mealy and lost flavor. The Sheriff and Walbridge discolored so badly as to render them unfit for show or market and declined very rapidly in the scale of points. The Fulton shriveled. The Milan, though a good keeper, lost color. The Snow retained color but many burst and after a few days became mealy. The Yellow Bell-Flower had decayed so badly at the time of the second marking that we were unable to get a specimen for exhibition. The Missouri Pippin, while remaining sound, lost color, thus reducing the scale. Salome remained firm upon the table. Fruit taken from storage and put upon the tables June 1 retained color and firmness for nearly 5 weeks."

A test was made of the comparative value of wrapping apples and storing them without wrapping. A few varieties each of Ben Davis and Winesap were placed in the cold-storage room in the fall with the other apples without being wrapped. The following June fully 70 per cent of the unwrapped apples were decayed and those remaining in a firm condition were so badly discolored and had lost flavor to such an extent as to render them wholly unfit for either show or market. "A few of the same varieties were wrapped simply in newspaper, not using waxed sheets. Of these about 30 per cent were in very poor condition June 1, while the same varieties picked and stored at the same time, using the double wrapping of waxed sheets and common paper, remained in almost perfect condition as late as November 1."

The date palm, J. W. TOUMEY (*Arizona Sta. Rpt. 1899, pp. 239, 240, figs. 2*).—Work on the date palm supplementary to that previously noted (E. S. R., 10, p. 851) is given. Samples of all the dates ripening in Arizona and specimens from California and Mexico were collected and weighed and analyzed with regard to the relative proportion of flesh to pit; and these data were compared with similar data obtained in the analyses of 6 samples of commercial dates collected in the open market. In a study of seedling dates grown in Arizona in the fall of 1898, less than 40 per cent were found edible and only about 10 per cent could be considered acceptable. Bartlett and Bennett seedlings compared favorably with fair grades of imported dates. They were of "excellent quality and flavor and of fair size . . . Of the 2 imported dates on the station farm that fruited the past season the variety 'Amreeyeh,' a dark date, was of fair flavor and quality. The pit, however, was exceptionally large. The fruit borne by the variety 'Seewah,' a light date, was of fair size and the pit medium, but the flesh was dry and stringy. Lack of sufficient irrigation probably accounts for the unsatisfactory condition of the fruit."

Work in cooperation with this Department is in progress toward the establishment of a 15-acre date orchard in the Salt River Valley.

Report of the horticulturist of the Nova Scotia Experimental Farm, W. S. BLAIR (*Canada Expt. Farms Rpts. 1898, pp. 263–270, pls. 2*).—Notes on ornamental plants, vegetables, and small fruits.

Report of the superintendent of the experimental farm for Manitoba, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1898, pp. 303–308, 313–325, pl. 1*).—Notes on the fruits, vegetables, and flowers at the station. A large number of crossbred apples have been planted for the purpose of selecting more hardy varieties.

Report of the superintendent of the experimental farm for Northwest Territories, A. MACKAY (*Canada Expt. Farms Rpts. 1898, pp. 352–358, 361–368, pls. 2*).—Notes on vegetables, ornamental plants, and fruits. Tests have been made of grafting new crossbred varieties of apples on *Pyrus baccata* and *P. prunifolia* roots. Many of the grafts did not grow. No general statement of the results is made.

Report of the superintendent of the experimental farm for British Columbia, T. A. SHARPE (*Canada Expt. Farms Rpts. 1898, pp. 393–412, pl. 1*).—Notes on a large number of varieties of apples, pears, plums, cherries, currants, raspberries, blackberries, and strawberries.

Effect and limitations of grafting, D. B. MILLER (*Trans. Indiana Hort. Soc. 1898, pp. 182–186*).—The interrelation of stock and scion is discussed. The report is based on experiments made at Purdue University in grafting tomatoes on potatoes, gooseberries on currants, box elder on honey locust, apples on peaches, peaches on currants, grapes on peaches, apples on honey locust, and box elder on peaches and walnuts.

Garden vegetables and melons, A. J. MCCLATCHIE (*Arizona Sta. Rpt. 1899, pp. 252–255*).—Brief notes are given on the growth of string beans, cabbage, sweet corn, lettuce, peas, squashes, tomatoes, spinach, turnips, beets, radishes, carrots, eggplants, and onions, with tabulated data for tests as to the yields of 43 varieties of melons which had ripened fruit up to July 4. Some of the Russian varieties of melons under cultivation at the station for the first time are proving superior, as regards earliness and yield, to older station sorts.

Water-culture experiments with kohl-rabi to determine the plant foods necessary in the head formation of this plant, R. OTTO (*Ber. Deut. Bot. Gesell., 17 (1899), No. 4, pp. 139-144*).

Self-sterility—an orchard problem, S. W. FLETCHER (*Proc. New Jersey State Hort. Soc. 1899, pp. 130-158*).

Nomenclature, S. A. BEACH (*Proc. Western New York Hort. Soc. 1899, pp. 88-96*).—A list is given of the synonyms of a large number of orchard and small fruits, with remarks on horticultural nomenclature.

The development of the buds in some of our common orchard fruits, W. R. LAZENBY (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 138-142*).—The characteristics of the fruit and leaf buds of peaches, apricots, apples, plums, pears, cherries, grapes, blackberries, raspberries, and quinces are discussed.

Oregon fruits, wild and cultivated, J. R. CALDWELL (*Oregon Bd. Hort. Rpt. 1898, pp. 336-348*).

Some principles bearing on the amelioration of fruits, J. CRAIG (*Trans. Indiana Hort. Soc. 1898, pp. 202-207*).

Fruit trees along highways, E. RATOIN (*Rev. Sci. [Paris], 4. ser., 12 (1899), No. 15, pp. 467-470*).—The relative profitableness of growing fruit and forest trees along public highways is considered. The discussion is based on the cost of planting, care and management, and returns of several highways in different European states. On the whole the greatest profits have resulted from planting fruit trees.

Pruning and cultivating the peach, R. MORRILL (*Proc. Western New York Hort. Soc. 1899, pp. 52-57*).—The author gives his method of cultivating, pruning, and managing a 100-acre peach orchard in Michigan.

A comparison of some varieties of plums, W. J. GREEN (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 144-148*).—Varieties of plums in the different groups of European, Japanese, and American plums, are discussed with regard to period of ripening, size, beauty, and quality of fruit, prolificness and precocity of trees, susceptibility to attacks of diseases and insects, and hardiness. Lists of suitable varieties for market and home use are given.

Notes on the edible berries of Alaska (*Plant World, 3 (1900), No. 2, pp. 17-19*).—The author describes a number of wild and cultivated berries found in Alaska and notes their use as food by the natives and other residents.

Variety tests of strawberries, W. B. ALWOOD and H. L. PRICE (*Virginia Sta. Bul. 91, pp. 81-94*).—Tabulated data for tests of 91 varieties with descriptive notes on each variety. The following were found to be the most promising varieties: "*Early*—Early Sunrise, Great Pacific, Darling. *Medium early*—Bismark, Clyde, Cobden Queen, Drouth King, Greenville, Maytrot, Mele, Mexican, Noland, and Tennessee. *Late*—Bethel, Enormous, Gandy, Jerry Rusk, Lady Franklin, Marguerite (home use), Marietta, Orewiler, and Splendid."

Fruit evaporation, H. E. DOSCH (*Oregon Bd. Hort. Rpt. 1898, pp. 440-446*).—Directions based on experience are given for evaporating prunes, pears, and apples.

Coffee, culture and preparation for market, H. LECOMTE (*Le café, culture, manipulation et production. Paris: Carré & Naud, 1899, pp. VI+344*).

The principles of pruning the coffee tree, A. CHATIN (*Rev. Agr. Réunion, 5 (1899), No. 10, pp. 441-446*).—This article outlines a rational method of coffee pruning, as suggested by a study of the life history of the plant. In order to overcome the habit which the tree has of fruiting principally on alternate years, especially in the earlier stages of its life history, the author recommends the removal of a part of one of the two primary branches of each cluster at the end of its first year of growth and before the appearance of the flower buds.

Viticulture as an agricultural industry, C. MAYER (*Agr. Jour. Cape Good Hope, 15 (1899), No. 10, pp. 645-651*).—The extent and profits of this industry in Cape Colony are considered.

Viticulture in the United States (*Bol. Not. Agr., 27 (1899) No. 27-28, pp. 951-1027, figs. 47*).—A comprehensive review of the grape and wine industry in the United States.

The Baltet pruning tables—the proper pruning of flowering shrubs, C. W. SEELYE (*Proc. Western New York Hort. Soc. 1899, pp. 47-52*).—Alphabetical arrangement of small trees and flowering shrubs into groups, according to the season when they are best pruned.

Cannas—the varieties to select and how to grow them, H. BALLOU (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 133-135*).—The characteristics of a number of varieties of cannas are noted and suggestions given regarding canna culture.

Helleborus, or Christmas rose, K. C. DAVIS (*Amer. Gard., 21 (1900), No. 265, pp. 40, 41, fig. 1*).—Key to garden species and varieties of Helleborus.

Commercial violet culture, a treatise on the growing and marketing of violets for profit, B. T. GALLOWAY (*New York: A. T. de La Mare Printing and Publishing Co., 1899, pp. 224, figs. 61*).—The author has endeavored to give every necessary detail of handling the soil, erection of houses and frames, management of the plants as regards propagating, selecting, cleaning, watering, etc.; the temperature conditions and ventilation, and directions for handling and marketing the crop. The diseases and insect enemies of violets and methods of combating them are considered at some length, and estimates made of the cost of production of violets and the profits in the business.

Ornamental trees and shrubs, C. C. LANEY (*Proc. Western New York Hort Soc. 1899, pp. 97-102*).—Descriptions and recommendations of a large number of desirable ornamental trees and shrubs for planting.

Tree life in cities (*Gardening, 8 (1899), No. 175, pp. 98, 99*).—Observations on different species of shade trees growing in the streets of Philadelphia.

Trees for avenue planting, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1898, p. 310*).—Three kinds of trees have been used for this purpose and at the present time 3 miles of roads have been improved by planting double rows of the trees, the kinds used being the native ash-leaved maple, native spruce, and Russian poplar (*Populus bercolensis*).

Landscape gardening as applied to home decoration, S. T. MAYNARD (*New York: John Wiley & Sons, 1899, pp. 338, figs. 168*).—This book treats of all the usual problems involved in the art of landscape gardening, and is accompanied with numerous illustrations and designs. Considerable space is given to the culture, care and management, and description of a large number of the more desirable ornamental trees, shrubs, hardy herbaceous plants, bedding plants, climbers, hardy ferns, ornamental grasses, and aquatic plants. Country roads, walks, drives, parks, school yards, improvement of old homes, and the like are considered; and chapters given on the insects and diseases injurious to ornamentals, and on the home fruit garden.

How to plan the home grounds, S. PARSONS, JR. (*New York: Doubleday & McClure Co., 1899, pp. 249, figs. 56*).—"The purpose of this book is to set forth briefly some simple basic principles concerning the processes whereby home grounds can be made beautiful." In Part I of the work, suggestions are given regarding the selection of the home grounds and the location of the site for the home, the roads, paths, lawns, flower gardens, and terraces; the selection of deciduous and evergreen trees, hardy herbaceous plants, vines and climbers, bedding plants, and aquatic plants for pools and streams; and the ornamental use of rocks, fences, bridges, summerhouses, etc. Plantations and residential parks are also considered, and sample forms of contracts and specifications for laying out parks, etc., given, together with a list of plants for general use on home grounds. The list of best trees and shrubs given is considered by the author as being one of the most important features of the work.

Part II is occupied chiefly with brief considerations of parks, cemeteries, and railroad stations, as typical examples of the more extended development of basic principles involved in landscape gardening of home grounds.

Landscape gardening, F. A. WAUGH (*New York: Orange Judd Co., 1899, pp. 152, figs. 35*).—A "treatise on the general principles governing outdoor art; with sundry suggestions for their application in the commoner problems of gardening." Part 1 of this work considers briefly the art and the artist; part 2 discusses rather comprehensively the artistic qualities of landscape composition; part 3 takes up the general problems involved and the application of the art in entrances, drives, walks, streets, avenues, suburban lots, farm yards, school yards, public parks, and in the use of water; and part 4 considers the gardener's materials; select trees, shrubs, hardy perennials, desirable annuals, bulbous plants, and climbers are briefly described and their use pointed out. The work concludes with a bibliography of 11 European and 11 American books on the subject.

FORESTRY.

Notes on the forest conditions of Porto Rico, R. T. HILL (*U. S. Dept. Agr., Division of Forestry Bul. 25, pp. 48, pls. 8, figs. 9*).—This report is a preliminary statement concerning the forests and forest conditions as observed by the author in a rapid reconnoissance of the island. The natural conditions affecting forest growth, such as configuration, geological formation, and climate, are discussed at some length.

The forest aspects of the island and the floras of the different regions are described. The characteristics of 15 of the principal woods are given at some length and the other forest-tree products are commented upon. Notes are given in which methods of lumbering are described, and some of the problems of reforestation are set forth. The island is said to be almost wholly without virgin forest, but the author thinks by proper management the present condition of barren mountain sides could be speedily covered with productive trees.

Forest trees, A. MACKAY (*Canada Expt. Farm Rpts. 1898, pp. 358–361, pl. 1*).—Notes are given on the present condition of a number of the forest tree and experimental plats at the Northwest Territories Experimental Farm. Among those most promising are the American cottonwood (*Populus deltoides*), the Russian poplar (*P. bereolensis*), and the ash-leaved maple.

A report is also given of the cost of planting and maintaining half-acre plats of box elder and green ash for 4 years. The trees were set out at distances of 2½, 3, 3½, and 4 ft., in each direction. The cost of planting and maintaining for 4 years ranged from $6.55 to $7.60 per half acre.

Two additional half-acre plats were seeded in rows 2½ ft. apart with box-elder and green-ash seed, the cost of sowing and maintaining for 4 years for the 2 lots being $5.92 and $9.06, respectively.

Notes are given on the number of species of trees and shrubs which have been planted in the arboretum, and the varieties and species added in 1898 are mentioned in detail. The total number of species and varieties is now 230.

Cost of planting and maintaining forest trees, S. A. Bedford (*Canada Expt. Farms Rpts. 1898, pp. 309, 310*).—In the spring of 1895 a plantation of 1 acre was planted with two-year-old seedlings of the native ash-leaved maple and white elm, the object being to ascertain the cost of planting and maintaining an acre of trees until they are large enough to shade the ground.

The cost of planting and maintaining the plantation for 4 years is given in detail, from which it appears that it had been maintained at a total cost of $16.25 per acre.

Another experiment of this sort has been begun with elm, maple, and ash, with alternate rows of sand cherry, the object being to ascertain how quickly the sand cherry will shade the ground and save the labor of further cultivation.

The heating capacity of wood (*Queensland Agr. Jour., 4 (1899), No. 7, pp. 105*).—In a brief quotation, the common supposition that the heating capacity of hard wood is greater than that of soft wood is corrected. It is claimed that repeated investigations have shown that the greatest heating power for a given quantity is possessed by one of the softest varieties of wood, namely the linden. Representing the heating capacity of this wood by 1, others reported upon would rank as follows: Fir 0.99, elm and pine 0.98, willow, chestnut, and larch 0.97, maple and spruce fir 0.96, black poplar 0.95, alder and white birch 0.94, oak 0.92, locust and white beech 0.91, and red beech 0.90.

The United States forest ranger system, B. Hermann (*Forester, 5 (1899), No. 9, pp. 195–199*).—An account is given of the management of the national forest reserves which are located in 11 States and Territories and contain an aggregate of about 46 million acres. The general plan shows that they are under the control of a superintendent and supervisor and a number of rangers. The latter patrol the district to extinguish fires and report on various infractions of the law.

The reserves are distributed as follows: Arizona—Grand Canyon, San Francisco Mountain, Black Mesa, and Prescott reserves; New Mexico—Pecos River and Bitter River reserves; Northern California—Stanislaus, Sierra, and Lake Tahoe forest reserves; Southern California—Pine Mountain, Zaca Lake, San Bernardino, San Gabriel, San Jacinto, and Trabuco Canyon reserves; Colorado—Battlement Mesa, Pikes Peak, Plum Creek, South Platte, and White River Plateau reserves; Utah—Fish Lake and Uintah reserves; Idaho—Bitter Root and Priest River reserves; Montana—Bitter Root, Flathead, Lewis and Clarke, and Gallatin reserves; Oregon—Cascade Range, Bull Run, and Ashland reserves; Dakota and Wyoming—Black Hills, Teton, Yellowstone National Park, and Big Horn reserves; and Washington—Priest River, Olympic, and Mount Rainier reserves.

Wood seasoning by electricity, E. T. Liefeld (*U. S. Consular Rpts. 1899, No. 226, pp. 499, 500*).—A description is given of a new process of seasoning wood and timber by electricity. The effect of the electric treatment seems to be to expel the sap and replace it by insoluble matter, by which the resistance and tenacity of the wood is increased and the liability to decay diminished. A solution consisting of 10 per cent of borax, 5 per cent of resin, and 0.75 per cent of carbonate of soda is used, and when the current is turned on the solution is said to replace the sap of the log.

A primer of forestry, G. Pinchot (*U. S. Dept. Agr., Division of Forestry Bul. 24, pp. 88, pls. 47, figs. 83*).—This is the first of a series of primers relating to forestry and trees of the forest, and deals with the units which compose the forest and its character as an organic whole. The enemies of forests are described at considerable length. The tree as an individual and as a community is described, and the various enemies before us are described.

Forest trees, S. A. Bedford (*Canada Expt. Farms Rpts. 1898, p. 309*).—A report is given of the condition of trees on the shelter belts and plantations conducted at the experimental farm at Manitoba. A list of trees is given which are believed to be most suitable for general planting in that region, as follows: Russian poplar (*Populus petrowskiana*), cut-leaved birch (*Betula alba laciniata*), dwarf birch (*B. pumila*), American alder (*Alnus viridis*), Rocky Mountain spruce (*Picea pungens*), European larch (*Larix europaea*), and *Thuya occidentalis elwangeriana.* All of these trees are reported as growing with great rapidity and withstanding the winters of that region.

Notes on a late oak, A. Jolyet (*Bul. Soc. Sci. Nancy, 2. ser., 14 (1898), No. 33, pp. 127–132, pls. 4*).—An account is given of a cultural variety of *Quercus pedunculata.* This variety, by leafing and flowering later than the species, is less liable to injury from late frosts. It is said to be less attacked by insects than other oaks.

Eucalypti, A. J. McClatchie (*Arizona Sta. Rpt. 1899, pp. 255–257*).—Work with these trees has been conducted along lines of "(1) Identification of trees of the various species now growing in the region; (2) propagation of young seedlings for planting, and (3) testing of a large number of species secured from California." All the results thus far secured point to *Eucalyptus rostrata* as the species best adapted to the climate of Arizona.

Miscellaneous notes, S. A. Bedford (*Canada Expt. Farms Rpts. 1898, pp. 310–313*).—Notes are given on the arboretum, condition of the trees, additions during the year covered by the report, descriptions of a number of hardy ornamental shrubs and hedge plants, and a report on the distribution of tree cuttings, 25,000 of which were prepared and sent out.

SEEDS—WEEDS.

The resistance of seed to high temperatures, V. Jodin (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 22, pp. 898, 899*).—It is stated that seed of wheat in vacuum may be heated to 100° C. without destroying its germinative power. Similar results may be obtained without the use of a vacuum if the temperature be gradually raised and the hygrometric relation between the seed and the air properly controlled. Pea and cress seeds heated directly for 6 hours at 98° C. were killed, but heated for 24 hours at 60° and afterwards to 98° they retained their germination to a considerable extent, 30 per cent of the peas and 60 per cent of the cress seeds germinating.

It is further shown that pea and cress seeds heated in sealed tubes to 40° C. lost their germinative power after about 20 days, but when quicklime or some other drying agent was introduced with the seed they were kept at 40° for 206 days without in any way diminishing their germinative ability. The author states that it is a practice in the museum of his laboratory to mix plaster or lime with seeds and that their germination is not impaired.

The influence of intermittent temperature on germination, J. VANHA (*Ztschr. Landw. Versuchw. Oesterr., 1 (1898), p. 91; abs. in Ann. Agron., 25 (1899), No. 11, pp. 559, 560*).—A report is given of experiments conducted with seed of *Poa pratensis*, in which different lots of seed were successively subjected to temperatures of 4, 11, 19, 27, and 35° C. for different lengths of time, varying from 4 to 16 hours per day. The beneficial influence of changing the temperature was noted whenever the temperature did not fall below 11° or rise above 35°. The best results were obtained by raising the temperature from 19 to 27°. The check experiments gave the best results at 27°, with 4° as the minimum and 35° as a maximum for germination. The results obtained with the checks were decidedly inferior to the others, and the best results were obtained in subjecting the seed to temperatures of 16, 22 to 27, and 34°, the last to be maintained for 4 or 5 hours per day.

According to the investigations of Liebenberg, intermittent temperature exercises a favorable action upon the genera: Poa and Agrostis, Dactylis, Anthoxanthum, Festuca, Alopecurus, Cynosurus, Daucus, Anethum, Ornithopus, Alnus, Betula, Beta, and conifers.

The vitality of seeds twenty years in the soil, W. J. BEAL (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 113, 114*).—In a paper read before the Association for the Promotion of Agricultural Science at its meeting August 19, 1899, the author gives results of the examination of seeds that have been buried for 20 years in the soil. The seeds were placed in 8-oz. bottles, mixed with sand, and buried at a depth of 20 in., the open mouths of the bottles slanting downward. A previous report on a similar experiment covering 15 years (E. S. R., 6, p. 539) gave conclusions similar to those in the present article. The seeds of 22 species of plants, mostly weed seeds, were tested, 50 seeds being used in every case. At the end of 20 years the following kinds and number of seeds germinated: Buckwheat, 4; black mustard, 9; shepherd's purse, 21; wild-pepper grass, 29; evening primrose, 14; smartweed, 1; narrow-leaved dock, 8; chickweed, 3, and mullein, 16.

The destruction of charlock, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 4, pp. 767-775*).—During the past season experiments were made over a considerable portion of Great Britain, in which spraying solutions of copper sulphate and iron sulphate for the destruction of charlock were tested. The author has brought together the reports of these experiments and summarized them.

In Northumberland and adjacent regions experiments on 17 different farms are reported in which preference was given to a 4 per cent solution of copper sulphate used at the rate of 40 gal. per acre. In Essex a 2 per cent solution of copper sulphate applied at the rate of 50 gal. per acre, in dry weather, when the plants were young, seemed to effectually destroy the weed without injury to other crops. It was sprayed upon crops of wheat, oats, barley, peas in bloom, cabbage, young clover, and tares, all of which were wholly uninjured; young peas, mangels, and beans were not permanently injured, but turnips were killed as quickly as the charlock.

Similar reports are given of experiments conducted at Cambridge, Sussex, Holmes Chapel, and Stamford, and a compilation is made of more than 200 additional trials throughout the country at large.

Summarizing all these experiments the author states that it can hardly be doubted that suitable spraying solutions are capable of destroying charlock to a very great extent when it occurs with other crops, without injury to the crops. Of spraying solutions, sulphate of copper is on the whole the best. Sulphate of iron is more uncertain and, though cheaper, requires a much larger quantity, so that the cost becomes about the same in either case. Successful spraying depends largely upon the conditions prevailing at the time. These are mainly the state of the weather and the age of the charlock. All experiments point to the conclusion that charlock should be sprayed in quite early stages, before the flower heads appear.

As regards the strength and quantity of solution opinions vary, but it appears that a 2 per cent solution at the rate of 40 gal. per acre will, as a rule, be successful in destroying the weeds when quite young, and a 3 or 4 per cent solution will be needed if the weeds are more advanced. The cost of materials and application will be from 75 cts. to $1 per acre.

How to test the vitality of garden seeds, A. S. Hitchcock (*Industrialist, 26 (1900), No. 19, p. 266*).—A brief description is given for the home testing of garden seeds, the method suggested being essentially that described in the Yearbook of this Department for 1895 (E. S. R., 8, p. 795). Appended is given a list of the average number of years that a number of the more common garden seeds will retain their vitality.

Seed testing, T. W. Kirk (*New Zealand Dept. Agr. Rpt. 1899, pp. 214-216*).—A tabular statement is given of the germinative ability of the seeds of a number of forage and other plants, in all about 150 tests being reported.

Tests of the vitality of grain and other seeds for 1898, W. Saunders (*Canada Expt. Farms Rpts. 1898, pp. 69-71*).—A report is given of 1,834 lots of seeds which were tested during the season of 1898 The average results of 6 years' testing of wheat, barley, and oats are given in tabular form, and the results of all the tests of seeds for vitality are tabulated. Tables are also given showing the results of grain tests for each of the Provinces.

Notes on weeds, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1899, pp. 222–227, figs. 3*).—Illustrated notes are given on pennyroyal (*Mentha pulegium*), which is said to be exceedingly troublesome on grass lands, nut grass, wild onion or sweet-scented garlic, bachelor's button, black nightshade, and native tobacco.

Weeds in pastures, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1899, pp. 216–218, fig. 1*).—Brief notes are given on the Canada thistle and the wild turnip. Experiments were conducted in which a 4 per cent solution of copper sulphate was sprayed at the rate of 25 gals. per acre over wheat and oat fields, and which resulted in killing the wild turnip without any injury to the crop. The same experiment is to be repeated on a larger scale.

The cocklebur, J. H. MAIDEN (*Dept. Agr. New South Wales, Misc. Pub. 332, pp. 5, pl. 1*).—Notes are given on the introduction and distribution of *Xanthium strumarium* in Australia, and its eradication by destroying the plants before seed maturity is advised.

The passing of the Russian thistle, C. E. BESSEY (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 135–137*).—In this paper, which was read before the Association for the Promotion of Agricultural Science at its meeting in August, 1899, the author states that in a recent journey of nearly 1,000 miles through a region once badly infested by the Russian thistle he found this weed to be of relatively much less importance than formerly. On fallow ground it still grows large and assumes a spherical form, but ordinarily it is low and slender. On ordinary farms it is said that the weed finds little opportunity for troublesome growth. Many farmers and ranchmen are said to esteem it as a fodder plant when fed early, and the author believes that the time may come when the sheep growers on the plains will undertake growing the Russian thistle as a fodder plant.

DISEASES OF PLANTS.

The crown gall, J. W. TOUMEY (*Arizona Sta. Rpt. 1899, pp. 235–238*).—For several years crown gall of deciduous fruit trees has been under investigation at the station. Field work has been conducted in an almond orchard at Glendale, Ariz., while experiments on seedling almonds, peaches, apricots, apples, walnuts, plums, and grapes were carried on in the station forcing house. So far no organism has been found to which the disease can be attributed. Many fungi have been observed at various stages of growth, but apparently all are present as saprophytes. Nematode worms are found abundantly occupying the soft tissue of the gall after it has begun to develop, but they are never found in the young galls.

A number of experiments have been undertaken to determine the communicability of the disease, which practically prove its contagious character. In one experiment almond seeds were planted mixed with several pounds of minced galls placed in the drills; another lot was placed in a similar manner mixed with minced galls and an equal weight of sulphur; a third lot of seed was mixed with minced galls and one-half their weight of copper sulphate; and an equal number of seeds were planted as a check. In each plat about 40 per cent of the seeds grew. In plats where the seeds were planted with minced galls 16 trees were diseased; in plats where the seeds were mixed with minced galls and sulphur 17 trees were diseased; and in plats where the seeds were mixed with minced galls and copper sulphate only 1 tree was diseased. In the check there were no diseased trees.

In the second experiment 12 seedlings from the check plat of the previous experiment were cut back and reset in the plat in which they originally grew. Before setting each seedling was treated with a small portion of rapidly growing gall crushed and inserted in a wound made at the crown of the seedling. A month later 10 of the seedlings had developed galls at the point of inoculation, while the other 2 did not develop them during the year they remained in the plat.

In the third experiment 4 seedlings were taken from the second experiment which bore galls less than 2 lines in diameter. At the end of 2 weeks the galls had grown to nearly an inch in diameter. One seedling from the above lot, bearing a small gall, was placed in a glass jar with water coming to but not covering it. After growing for about 6 weeks the gall had increased more than 10 times its original size.

In another experiment a number of almond seedlings, which had come up in an orchard, were examined, and although less than 2 per cent of the total number of seedlings were diseased, it was found that more than 80 per cent of these were in contact with or were within 1 foot of galls on the old trees.

The author believes that his investigations indicate the communicability of this disease, but as yet the specific cause of it is unknown. Precautionary measures should be taken in planting to obtain seedlings from uninfested regions. The author's experiments indicate that copper sulphate is the most effective application to prevent the root or crown gall. He recommends mixing a given weight of pulverized copper sulphate with twice its weight in lime, to which sufficient water is added to make the mixture of the consistency of paste. Remove the galls and cover the wounds with a thick layer of the paste. All galls removed should be gathered and burned.

A bacterial disease of the sugar beet, CLARA A. CUNNINGHAM (*Bot. Gaz., 28 (1899), No. 3, pp. 177-192, pls. 5*).—Late in 1890 a chemist of the Indiana Experiment Station is said to have noticed that some sugar beets showed a much lower percentage of sugar than others, and the difference seemed to be associated with a slight change in the usual appearance of the roots. A preliminary study was made of the disease and the results published in Bulletin 39 of the station (E. S. R., 3, p. 853). In the fall of 1896 the author reinvestigated this disease and was led to believe that there is no positive evidence that the bacterial disease of sugar-beet in Indiana is the same as that described as occurring in Europe.

The disease attacks the whole beet plant, causing a peculiar appearance of the leaf, so that with a little practice diseased beets can be distinguished readily from healthy ones when growing in the field. The outer, older leaves soon die away, and the intermediate and heart leaves are left wrinkled, curled, rather flabby, and of a yellowish-green color. The external appearance of a diseased beet root is not materially different from that of a healthy one. A decisive test for the disease in the roots, however, is found in the appearance of the fibrovascular bundles, since in the diseased roots they appear as dark rings in the white flesh and become almost black after being exposed to the air for a few minutes.

An account is given of the experiments conducted for the separation of the organism causing the disease, and details of inoculation experiments. The germ as isolated is a small bacillus measuring from 0.9 to 1.3 μ and 0.5 to 0.8 μ in diameter. In culture media the germs are arranged singly or in pairs and possess individual motion. They are easily stained with all the common bacterial stains, but no method showed the presence of spores or flagella. The effect of light on growth and the growth of the germ in different culture media are described at length.

Summarizing the results of the experiments, the author states that microscopical examination of the tissues of diseased beets reveals the presence of bacteria in the cells of the plant. The tissues of the plant are not broken down and the bacteria in all parts of the plant seem to be the same. Transfers of diseased tissue to healthy beet roots resulted in a changed appearance of the plants, which indicated that the disease was transmitted.

The manner in which the germ finds entrance into the plant has not been determined. The conditions most favorable to attack are those resulting from drought with succeeding low temperature. Experiments have shown that in a medium containing a small quantity of acid the germ grows nearly or quite as well as in an alkaline one. It converts cane sugar to glucose, with the production of gas. The amount of gas produced does not seem to be constant, but the reasons for this irregularity are yet to be determined.

Another organism was separated from the sugar beet, which consisted of colorless, gelatinous masses resembling the Leuconostoc so common in the vicinity of sugar refineries. Microscopic examinations failed to reveal the characteristics of the Leuconostoc. If it should prove to be a form of this organism, its occurrence in diseased beet roots would be a matter of interest.

A new disease of carnations, L. MANGIN (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 19, pp. 731–734*).—A description is given of a disease which has attacked carnations growing in the vicinity of Provence, Cannes, Nice, and Antibes. The diseased plants are recognized at once by the yellowish color and wilted condition of the leaves. The roots seemed sound, but the base of the stem is in a more or less advanced state of decomposition. The plants frequently rot off at the surface of the soil. Examinations of the tissues revealed a great number of fungi, among them being molds and a mycelium of a number of other fungi, bacteria, and eelworms, among them being Tylenchus and Rhabditis.

On account of the great number of possible causes, the author has examined them in considerable detail, and is led to the conclusion that the disease is due to the mycelium of some fungus, the exact nature of the parasite not being given. It seems probable that it is distributed through cuttings, and on this account it is recommended that before planting all cuttings should be placed for a short time in a solution of copper sulphate, 1 or 2 gm. per liter, or in a solution containing 15 gm. of naphthol and 45 gm. of soap per liter. By this operation all spores will be killed

Notes on plant diseases, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1899, pp. 227–231, pl. 1, figs. 2*).—Notes are given on the verrucosis of the lemon and other citrus trees, gooseberry-leaf spot, and gooseberry mildew, with suggestions as to the best remedies for combating them.

The black or summer rust of wheat, O. LUGGER (*Minnesota Sta. Bul. 64, pp. 535–550, figs. 13*).—A popular statement is given of the cause of the rust of wheat and its method of attacking the host, and the relation between the stages on the wheat and the barberry are shown.

Certain potato diseases and their remedies, L. R. JONES (*Vermont Sta. Bul. 72, pp. 32, figs. 17*).—This bulletin, which contains a résumé of the work done at the station in investigating certain potato diseases and their remedies in 1889–1899, is a revision and compilation from the previous publications of the station, especially of Bulletin 19 (E. S. R., 8, p. 138) and the report for 1895 (E. S. R., 8, p. 992).

A new potato disease, H. MARSHALL WARD (*Trans. British Mycol. Soc. 1897–98, pp. 47–50*).

A scab disease of sugar beets, FRANK (*Braunschweig. Landw. Ztg., 67 (1899), No. 51, pp. 228, 229, fig. 1*).—A characteristic disease is described in which the sugar beets are infested in rather definite zones with a deep scab formation. The cause of the disease is thought to be a species of Tylenchus.

A bacterial disease of the lupine, D. HEGYI (*Kiserlet. Közlem., 2 (1899), No. 5, pp. 232–235, figs. 2*).—Describes *Bacillus elegans*, n. sp., as causing a serious disease of lupines.

Bacteriosis of the tomato, D. HEGYI (*Kiserlet. Közlem., 2 (1899), No. 5, pp. 230, 231, figs. 2*).—Describes *Bacillus lycopersici* as causing a rot of tomato fruits, etc.

Combating the leaf diseases of orchard trees, grapes, etc., E. JOKISCH (*Mitt. K. K. Gartenbau Gesell. Steiermark, 1899, No. 6, pp. 115, 116*).

Grape anthracnose, T. W. KIRK (*New Zealand Dept. Agr. Rpt. 1899, pp. 219–222, pl. 1*).—Illustrated notes are given of the grape anthracnose due to *Sphaceloma ampelinum*, and the best remedies for prevention are suggested. Formulas and directions for the preparation of Bordeaux mixture and copper carbonate solution are given.

Anthracnose of grapes, J. M. HEURGO (*Minn. Agr. Argentine Republic, 1899, pp. 28, pl. 1, figs. 4*).—Describes the cause of the disease and suggests the use of fungicides for its prevention.

A disease of plane trees in the Luxemburg Gardens, A. GIARD (*Compt. Rend. Soc. Biol., 11. ser., 1 (1899), No. 23, pp. 565, 566*).—An attack of *Glœosporium* sp. is described.

Concerning the parasitic fungus which causes the wart disease of Japanese pines, M. SHIRAI (*Bot. Mag. [Tokyo], 13 (1899), No. 147, pp. 153–158*).

On the use of weak solutions of copper sulphate as a fungicide, G. BATTANCHON (*Vigne Amér. et Viticult. Europe, 23 (1899), No. 3, p. 72; abs. in Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No 22, pp. 789, 790*).—The author states that at least 10,000 tons of copper sulphate has been used as a fungicide in the Department of Hérault. He believes that weaker solutions both when used alone and in Bordeaux mixture would be as efficient, cheaper, and often prevent the serious injury of too strong solutions.

Copper fungicides used at Montportail, F. SIMONET (*Vigne Amér. et Viticult. Europe, 23 (1899), No. 5, p. 152; abs. in Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 22, p. 790*).—According to the abstract the efficiency of the fungicides for the prevention of Peronospora and black rot as shown by several years' testing was in the following order: Bordeaux mixture with sugar, Lavergne mixture, Bordeaux mixture with albumin, simple Bordeaux mixture, Burgundy mixture, bicarbonate of soda mixture, neutral verdigris solution, and Bordeaux mixture and molasses.

Notes upon injury to fruit trees caused by fungicides, F. MÜLLER (*Prakt. Bl. Pflanzenschutz, 2 (1899), No. 9, pp. 65-67*).

ENTOMOLOGY.

Report of the entomologist and botanist, J. FLETCHER (*Canada Expt. Farms Rpts. 1898, pp. 167-219*).—The author gives a somewhat extended discussion of the insects injurious to cereals. The wheat midge (*Diplosis tritici*) is reported as having caused considerable damage during the past year. The remedies suggested are the burning of all rubbish and deep plowing.

Biological notes are given of the Hessian fly (*Cecidomyia destructor*). The remedies to be relied upon are late sowing, burning of refuse, destruction of the stubble, and the application of a quick-acting fertilizer.

The wheat stem maggot (*Meromyza americana*) is described and figured. Three broods appear annually in the region of Ottawa, one at the beginning of June, the second at the end of July, and the third at the end of September. The author recommends the application of special fertilizers as a top-dressing, the sowing of a few drills of wheat or barley along the infested fields as trap crops, and the destruction of these trap crops.

The author gives biological and economic notes on the American frit fly (*Oscinis carbonaria*), with which the wheat stem maggot and Hessian fly are compared in both the larval and pupal conditions, jointworms (Isosoma), grain aphis, the wheat stem sawfly (*Cephus pygmæus*), and various species of cutworms.

The Rocky Mountain locust is described and figured. The author relates the various features of the life history and habits of this insect with references to the literature on the subject. The remedies to be applied are deep plowing in the spring or fall of the areas where the eggs are laid and the use of hopper dozers.

Among insects injurious to vegetables the author gives an account of 2 species of cutworms. The black army worm (*Noctua fennica*) is said to have committed serious depredations upon garden and field crops. The remedies which were successfully tried and are recommended are the same as those applied against outbreaks of the true army worm. *Carneades scandens* were found in large numbers in gardens in Ottawa. Brief notes are given on the habits of this species. As remedies against this insect the author recommends the banding of freshly set out annual plants with paper or tin rings and the use of poisoned bran which consists of a mixture of Paris green and bran in the proportion of 1:50. *Calosoma calidum* is mentioned as an especially destructive enemy of these cutworms.

Observations were made on the habits and life history of the pea moth (*Semasia nigricana*), pea weevil, bean weevil, carrot rust fly (*Psoila rosæ*), *Aphis brassicæ*, and the cabbage-root maggot. As a remedy for controlling the carrot rust fly, the author recommends spraying with kerosene emulsion, or sprinkling along the rows with a land plaster or ashes mixed with dry sand.

The four-lined leaf-bug (*Pœcilocapsus lineatus*) is reported as having been especially destructive to potatoes. The remedies which are recommended are kerosene emulsion as a spray upon the nymphs, jarring the nymphs and perfect insects from the plants into open tins containing kerosene oil, and the destruction of the eggs which are laid on the twigs of the bushes.

The apple-fruit miner (*Argyresthia conjugella*) is recorded as still doing considerable damage in parts of British Columbia. Brief notes with recommendations on the usual remedies are given for *Grapholitha prunivora*, tent caterpillars (*Clisiocampa disstria* and *C. americana*), plum curculio, species of Xylina, San José scale, cherry aphis, green apple aphis, and the bronze apple tree weevil (*Magdalis ænescens*).

Xylocrius agassizii is reported as having been introduced from Oregon into Victoria and to have attacked the stems of the gooseberry. Its native food plants are the various species of Ribes. The insect is rare even in its home on the Pacific slope, and the author does not fear that it will become of serious economic importance. A general account is added on the necessity of spraying and upon the benefits to be derived from it.

J. Fixter makes a report on various experiments conducted in the apiary. Eight colonies of bees were wintered in a cellar upon shelves. The front entrances of the hives were left wide open, and the wooden covers were taken off and replaced with chaff. The temperature during the winter varied from 44 to 50° F. The bees lost on an average 9 lbs. per swarm during the winter. Two colonies which were placed in the cellar with the tops and bottoms left on, lost 14½ lbs. per hive and the combs were found to be damp and slightly moldy in the spring. Two colonies stored in a root house, with as much ventilation as it was possible to give them under the circumstances, lost 13 lbs. per hive, and there were some signs of dampness in the hives as well as dysentery among the bees. Two colonies were put into a pit on the side of a hill on November 12. From November to March the temperature did not fall below 38° nor go above 39°. The pit was opened March 26. Water had accumulated so as to come up on the sides of the hives. One hive survived, the other finally died out. Two colonies which were left in the house apiary with some additional packing flew quite extensively during warm days and lost 19½ lbs. and 16½ lbs., respectively, during the experiment.

In some experiments made with full sheets of foundation and half sheets it was found that the bees in every case worked first on the full sheets.

The entomologist gives a brief description of the horn fly (*Hæmatobia serrata*) with the recommendation of the following remedy: A mixture of 1 lb. of pine tar in 10 lbs. of lard.

The Hessian fly, O. LUGGER (*Minnesota Sta. Bul. 64, pp. 551–557, figs. 5*).—In this bulletin the author has summarized our present knowledge on the subject of the habits and life history of the Hessian fly. The remedies which have already been found more or less effective in controlling this insect are recommended for use. From certain observations which the author has made in Minnesota, it is believed that the insect in that State develops only one brood per year. Since the author believes that the Hessian fly in Minnesota passes the winter in the flaxseed stage, he recommends, especially, burning of the stubble where this is possible, and in case this remedy is not practicable, it is recommended that all wheat-stubble ground be plowed. The plowing should be done very soon after harvesting. A few of the parasites which are known to help in reducing the numbers of the Hessian fly are figured and briefly described.

Migratory locusts, or grasshoppers, O. LUGGER (*Minnesota Sta. Bul. 64, pp. 558–569, pls. 2, figs. 8*).—This article contains a popular account of the habits and of the devastation which is wrought by migratory locusts, dealing especially with 3 species, the Rocky Mountain locust, the lesser migratory locust (*Melanoplus atlanis*), and *Camnula pellucida*. The author briefly describes the method of egg-laying which is peculiar to the Rocky Mountain locust, and also mentions the situations in which the lesser migratory locust usually deposits its eggs The pellucid locust has rather different egg-laying habits. Ordinarily the eggs are deposited upon the surface of the soil, and are protected by grass and such rubbish as may be found in those situations. Occasionally the eggs are laid just beneath the surface, but this occurs only where the soil is loose.

The author describes certain features of these 3 species by means of which they can be identified. With regard to remedies, it is recommended that all cultivated ground, and especially stubble fields which are selected by the locusts for deposition of their eggs, be thoroughly plowed.

Some important insect enemies of cucurbits, A. L. QUAINTANCE (*Georgia Sta. Bul. 15, pp. 21–50, figs. 17*).—In this bulletin the author has given a general discussion of the habits, life history, distribution, natural enemies, and remedial and preventive measures of the following insects: Striped cucumber beetle (*Diabrotica vittata*), melon aphis (*Aphis gossypii*), pickle worm (*Margaronia nitidalis*), melon worm (*M. hyalinata*), the squash-vine borer, and the squash bug.

In studying the pickle worm, bottomless cages were placed over vines and fruits in the field in order to secure the most natural conditions. The insects deposited their eggs upon the glass and the woodwork of the breeding cages. No eggs were laid on the foliage or fruit of the canteloupes upon which the experiments were made. The eggs hatched in about 3 days and during warm weather the larvæ completed their growth within 14 days. The larvæ seemed to prefer the flowers and fruit of the squash.

In experiments made in the field, tobacco dust, pyrethrum powder, hellebore, carbolized lime, and a thick coating of Bordeaux mixture proved valueless. It is suggested that some protection may be secured by planting squash as a trap crop.

The author found that the melon worm appears in some seasons about June 15, and in other seasons as late as July 17. It is believed, therefore, that correspondents may have mistaken the pickle worm for the melon worm.

The moths of the squash-vine borer were observed as early as May 23 and as late as July 22. There seem to be 2 broods in the State each year, and the life cycle is about 2 months.

The forest tent caterpillar, V. H. LOWE (*New York State Sta. Bul. 159, pp. 33–60, pls. 6*).—In this bulletin the author presents an account of the systematic position of the tent caterpillar, a brief statement of the origin and distribution of the insect, and of the history of our knowledge concerning it. The first disastrous outbreaks of this insect in New York were in 1866 and 1867. In 1886, and again in 1889 and 1890, the insect was present in destructive numbers. In 1893 another outbreak occurred, especially in apple orchards. The outbreak of which this bulletin is an account was felt most severely along the western, northern, and eastern portions of the Adirondacks, the upper valley of the Hudson, and throughout Cortland, Chenango and Otsego counties. Besides the food plants upon which this insect has already been reported as depredating, the author adds ironwood to the list. Brief descriptions are given of the egg and the egg masses. It is stated that the latter were not as large as usual, containing as a rule only about 200 eggs. The eggs were laid the last week of June and the first week of July. The earliest caterpillars were seen about Geneva during the last week of March. The period of hatching extends over a month or more, and under normal conditions the caterpillars acquire their full size within 6 weeks. The author describes the feeding habits and the silk-spinning habit of the caterpillars. The forest tent caterpillar was observed sharing a nest with an apple-tree tent caterpillar. The first-named species, however, was never seen to enter the nest. The congregating habit of the caterpillar at times of molting is noted, and detailed descriptions are given of the caterpillars during their different stages between the molts. This insect usually pupates inside of rolled leaves, but it was observed to pupate in large numbers on fences, out-buildings, and even on the ground. The moths issued from the cocoons from June 26 until July 8. Two thousand five hundred cocoons were collected for observation. Out of this number, 794 produced male moths and 672 female moths; 312 of the cocoons were parasitized, and 722 did not hatch. It is thus seen that about 40 per cent of the cocoons failed to produce moths, and a little over 12½ per cent were parasitized The author reproduces detailed descriptions of the male and female moths as given by Dr. Fitch.

Among the birds which are reported as preying upon this insect may be mentioned the black-capped chickadee, yellow-billed cuckoo, Baltimore oriole, American red start, catbird, and robin. The more noteworthy insect enemies of the forest tent caterpillar include the following predaceous species: *Calosoma scrutator*, *C. calidum*, *Podisus placidus*, and *P. seriventris*. Among the parasitic insects which were bred from the cocoons we may note the following: *Pimpla conquisitor*, *P. pedalis*, *Theronia fulvescens*, and *Diglochis omnivorus*.

By way of artificial remedies against this insect the author recommends the following measures to be adopted: The destruction of the egg masses, spraying with an arsenical compound for poisoning the caterpillars, the destruction of the caterpillars while assembled in masses on the trunks and large branches, and the method of jarring and banding. For banding the tree the author recommends tar mixed with two parts of raw oil or raupenleim. The moths are readily attracted to the light and may thus be caught by a lantern trap. It may be advisable to collect the cocoons, but if this is done they should not be destroyed, but should be placed under a netting with meshes of such size as to allow the parasites to escape, but to prevent the escape of the moths. For spraying the larger shade trees it will be found advisable, where it can be afforded, to use steam power apparatus. A rather extensive bibliographical list of literature on this insect is appended to the bulletin.

The cherry fruit fly—a new cherry pest, M. V. SLINGERLAND (*New York Cornell Sta. Bul. 172, pp. 21-41, figs. 7*).—The larva of the fly, which is believed by the author to be *Rhagoletis cingulata*, has been found infesting cherries in one orchard of Massachusetts and in several of New York. The mature flies have not yet been bred from these maggots, and the provisional identification by the author may therefore prove to be incorrect. Adult flies of the species to which the larva are referred were noticed in considerable numbers about the cherry trees and upon the cherries. These flies were not observed depositing eggs nor were uninjured eggs secured for study. It is believed that the eggs are deposited either upon the skin of the cherry or just beneath the surface. The maggots feed upon the flesh of the ripening cherry near the pit. Ordinarily there is but a single maggot in each cherry, but occasionally a second smaller one was found. This pest attacks all varieties of cherries, whether sweet, sour, subacid, early, or late. One unfortunate feature of infestation by this insect is that the presence of the maggots within the cherries can not be surmised from the external appearance of the fruit. The insect has been reported from Belmont, Mass., Ithaca and Geneva, N. Y. Some cherry growers noticed this insect in their fruit last year, and the correspondent from Belmont, Mass., believes that his fruit has been infested for 4 or 5 years. From the incomplete observations which have been made upon the insect thus far it is believed there is only one brood per year.

No remedial measures have been undertaken as yet, but the author presents a summary of operations which have been conducted in Australia, South Africa, and Europe in the destruction of these insects. A brief bibliography of the subject is appended to the bulletin.

Second report of the State inspector for the San José scale, W. B. ALWOOD (*Richmond, 1899, pp. 34, map 1*).—This report contains a statement of the law according to which the State inspector of Virginia was appointed and of the rules and regulations for the government of the inspector and assistant inspectors in their work on the eradication of the San José scale. The inspection work thus far conducted in the State indicates the presence of the San José scale in 318 localities scattered over 36 counties. Tables are given showing the location of the different infected areas and the source from which the infection came. The author believes that the work of inspection in Virginia has materially lessened the distribution of the scale by means of interstate commerce. Attention is called to the necessity of thorough inspection and eradication methods in nurseries which have once become badly infested. Sixty-nine nurseries within the State have been inspected, and treatment against the San José scale has been carried out in the 9 nurseries which were found infested, with the result that the scale has apparently been eradicated in 5.

In experimental work with remedies against this insect, the author made use of all the better known remedies. For fumigation hydrocyanic-acid gas was produced according to the following formula: Fused potassium cyanid, 98 per cent, 1 oz.; commercial sulphuric acid, 1⅛ fluid oz.; water, 3 fluid oz. for each 100 cu. in. of space. It is stated that this formula is slightly stronger than is necessary, but is entirely safe with dormant plants.

A report is made on experiments conducted in one orchard which consisted of about 400 apple trees. Apparently the San José scale in this orchard had gradually spread from 4 original centers of infestation. The course of the distribution of the scale was in the direction in which the orchard was cultivated, and it is suggested that the spread of the scale, therefore, depended upon human agencies. The orchard was divided, for experimental purposes, into 3 sections, of which one was treated with Leggett's whale-oil soap, another with kerosene, and a third with Good's potash soap. Leggett's soap in the proportion of 2 lbs. to a gallon of water was applied March 12. It was applied at a temperature of 135° F. On December 24 of the same year, an inspection of this section of the orchard showed that the trees were in good condition and that the scales were all dead.

Upon the second section pure kerosene was sprayed on March 21 by means of a blast atomizer. The buds of the trees were swollen at the time. On March 28, the same trees were sprayed with a 30 per cent kerosene-water mixture. On December 24 of the same year an examination of these trees showed that the scales were dead and that no apparent injury had resulted to the trees.

Good's No. 3 soap was applied to section 3 in the same manner and at the same dates as in the treatment for section 1. An examination of this section of the orchard on December 24 of the same year disclosed the fact that the scales were apparently all dead and that all trees had escaped injury except one which would apparently die. On November 4 of the following year living San José scale were found upon one tree which had been treated with kerosene.

It was found impracticable during these experiments to apply by means of a spray machine any soap solution which contained 2 lbs. of soap to a gallon of water. At this strength the solution is too caustic and destroys the hose. The kerosene method is believed to be very effectual and is much the cheapest method of the three.

The San Jose scale law in Virginia empowers cities or counties to take special action regarding the extermination of the scale. Such action has been taken in a few cases and the author believes it is a valuable provision in the law. A list of plants which are known to serve as host plants for the San Jose scale is given, together with a list of publications of the Virginia Station and State inspector relative to the San José scale.

Crude petroleum as an insecticide, J. B. SMITH (*New Jersey Stas. Bul. 138, pp. 22, pls. 1*).—The use of crude petroleum as an insecticide was first suggested to the author by L. P. Schenck in the winter of 1897–98. This substance was believed to be dangerous to fruit trees and was therefore experimented with rather cautiously at first. A dwarf Duchess pear tree which was thickly incrusted with San José scale received an application of crude petroleum in January, 1898. All scales were destroyed and the tree remained uninjured. In March, 1898, the section of the orchard in which this tree stood was treated with a 30 per cent crude oil mixture. The growth of the trees seemed to be stimulated and no trace of injury from the insecticide was manifested. On March 15, a dozen pear trees in early stages of growth were sprayed. In this experiment some injury was produced, a few of the twigs being killed outright. As a winter application the insecticide had proved thus far very satisfactory. The author now requested certain horticulturists to make experiments as checks upon his own work. Henry Pfeiffer made application of crude petroleum to peach trees in a series of sprayings. The insecticide was applied March 27, 31, and April 14 and 28. No injury to the trees was produced by these applications. In another location 600 peach trees which were moderately infested with scale were sprayed with a 30 per cent mixture of crude petroleum and water during March. The scales were killed and the trees did not suffer from the application. Fifty gallons of oil were used upon the 600 trees and application was made by means of the Vermorel nozzle. Three peach trees which were sprayed early in April with 6 qts. of crude oil were freed from the San José scale by this application but were killed by the insecticide.

Currants, gooseberries, raspberries, and blackberries were sprayed with 30 per cent crude oil without injury to the plants. A number of young apple trees in the nursery row had become badly infested with San José scale and were taken out and painted with undiluted crude oil by means of a whitewash brush. The scales were all killed and the trees were without injury. Similar results were obtained in a plum orchard of 100 trees which was sprayed with undiluted oil.

Satisfactory experiments are reported from the use of an emulsion of crude petroleum made according to the following formula: Olein soap, 8 lbs.; crude petroleum, 40 qts.; water, 40 qts.

In all about 1,000 trees other than cherry were treated with crude petroleum either undiluted or mixed with from 60 to 70 parts of water. These trees varied in age from stock in the nursery row to old trees in full bearing. No cases of injury were reported from applications which were made in the winter. On the contrary, the trees seemed to show increased vigor. The fruit buds were not found to have been injured, although the observations on this point were not complete. The author concludes that crude petroleum is not suitable as a summer application, either pure or undiluted. This substance does not evaporate readily, and on small branches it ultimately passes around the whole branch, even when during the application it only touched one side. It does not usually penetrate through the superficial layer of bark, yet it remains as an oily covering for some weeks and the San José scale can not penetrate, even after the application has been upon the tree for a month. The author believes that crude petroleum is as effective in the destruction of scale insects as kerosene and that it is harmless even to the more tender varieties of fruit trees. It is recommended that when the oil is used in an undiluted form it should be applied with a Vermorel nozzle. Equally satisfactory results are obtained, however, when the crude oil is used mixed with from 60 to 75 per cent of water. Summer applications of the oil may be made upon the trunks and branches if care is exercised that the oil does not come in contact with the foliage. Close observation must be kept upon the emulsion sprayers, if such machines are used. It is found that they are often unreliable, throwing at times almost undiluted oil and at other times almost pure water.

Methods of producing honey, F. Greiner (*Trans. New York State Agr. Soc. and New York Bureau Farmers' Inst. Rpt. 1898, pp. 300–306*).—A discussion of the most suitable arrangement of frames and hives for a large production of honey.

Foul brood in bees, E. R. Root (*Trans. New York State Agr. Soc. and New York Bureau Farmers' Inst. Rpt. 1898, pp. 307–314*).—An account of the nature of foul brood, with a statement of treatment to be adopted against it. The laws of Wisconsin and New York regarding foul brood are appended to the article.

The respiratory products of the egg of the silkworm during normal incubation, E. Quajat (*Ann. R. Staz. Bacol. Padova, 27 (1899), pp. 57–81, pls. 2*).—An experimental study of this problem under various conditions of incubation, such as incubation with rapid and constant elevation of temperature, incubation in dry and humid atmosphere, and slow and gradual incubation with a comparison of the behavior of different races of silkworms under these conditions.

The influence of external conditions upon the physical properties of the cocoon of silkworms, E. Verson (*Ann. R. Staz. Bacol. Padova, 27 (1899), pp. 93–96*).

On the wintering and incubation of the egg of the silkworm, E. Quajat (*Ann. R. Staz. Bacol. Padova, 27 (1899), pp. 13–43*).—An experimental study of the following problems: The influence of estivation or of a long preparatory stage upon the duration of the period of hibernation, and a determination of the minimum time necessary for complete hibernation.

The action of "epicarin" upon the mange mites of dogs, Regenbogen (*Monatsh. Prakt. Thierh., 11 (1900), No. 4, pp. 145–149*).—This substance was found by experiment to have only a slight effect upon the mites.

The color relation between the pupæ of Papilio machaon, Pieris napi, and many other species and the surroundings of the larvæ preparing to pupate, F. Merrifield and E. B. Poulton (*Trans. Ent. Soc. London, 1899, pt. 4, pp. 369–433*).—A detailed account of experimental studies upon the interrelation between insects and their environments with regard to the influence of the intensity of light and the color of environment upon the color of the insects.

On sexual dimorphism in the rutelid genus Parastasia with descriptions of new species, G. J. Arrow (*Trans. Ent. Soc. London, 1899, pt. 4, pp. 479–499 pl. 1*).—An account of the striking differences in size and occurrence of the two sexes of the species belonging to Parastasia.

Dimorphism in the two sexes of a new species of Cecidomyidæ, J. C. H. De Meijere (*Tijdschr. Ent., 42 (1899), No. 3, pp. 140–152, pls. 2*).—A study of this phenomenon in a species of Monardia.

On the metamorphosis of insects, C. Perez (*Bul. Soc. Ent. France, 1899, No. 20, pp. 398–402*).—A study of the action of the leucocytes in ants and Tineidæ during metamorphosis.

The ants of Madagascar collected by A. Mocquerys, C. Emery (*Bul. Soc. Ent. Ital., 31 (1899), No. 1–4, pp. 263–290, figs. 8*).—Descriptive and biological notes upon a number of species, some of which are here described for the first time.

The visitors of the Caprifoliaceæ, J. H. Lovell (*Amer. Nat., 34 (1900), No. 397, pp. 37–51*).—Notes on the insect visitors of a number of species belonging to this family of plants.

Hop dogs, F. V. Theobald (*Jour. Southeast. Agr. Col., Wye, 1899, No 8, pp. 35–38*).—Economic and biological notes on *Dasychira pudibunda*, *Orgyia antiqua*, and *Porthecia auriflua*.

Injurious fruit insects, R. Goethe (*Ber. K. Lehranst. Obst., Wein u. Gartenbau, Geisenheim, 1898–99, pp. 16–24, figs. 3*).—Notes on *Aspidiotus ostreæformis*, *A. scutiformis*, *Diaspis fallax*, species of Parlatoria, *Schizoneura lanigera*, and *Anthonomus pomorum*.

Fruit flies, T. W. Kirk (*New Zealand Dept. Agr. Rpt. 1899, pp. 232–234, figs. 7*).—Notes on *Tephritis tryoni* and *Halterophora capitata*.

The "cankerworm," G. Allen (*Sci. Amer. Sup., 49 (1900), No. 1255, pp. 20122–20124, figs. 19; reprinted from the Strand Magazine*).—A popular account of the periodical cicada and the army worm.

Experiments in fighting the woolly aphis, Schellenberger (*Fühling's Landw. Ztg., 48 (1899), No. 18, pp. 696, 697*).

A pest of woodland and grove, F. H. Hall and V. H. Lowe (*New York State Sta. Bul. 159, popular ed., pp. 6, figs. 3*).—This is a popular summary of Bulletin 159 of the station (E. S. R., 11, p. 865).

The destructive green-peà louse, W. G. Johnson (*Canad. Ent., 32 (1900), No. 2, pp. 56–60, figs. 3*).—Notes on the habits and life history of *Nectarophora destructor. Bassus lætorius* was bred from this insect. Ladybirds, Syrphus flies, and lacewings were observed as predaceous enemies of the louse.

The insect foes of tobacco (*Sci. Amer. Sup., 49 (1900), No. 1257, pp. 20146, 20147 figs. 5*).—Notes on *Protoparce celeus, Epitrix parvula, Heliothis armigera, Lasioderma serricorne, Œcanthus niveus*, and other insects injurious to tobacco.

A new insect pest, J. Chamberlain (*Sci. Amer., 82 (1900), No. 3, p. 42*).—An account of the damage done to white birch by *Agrilus anxius* in Buffalo and vicinity.

Notes and descriptions of some species of western Australian Coccidæ, C. Fuller (*Trans. Ent. Soc. London, 1899, pt. 4, pp. 435–473, pl. 1*).—Notes upon about 100 species of Coccidæ, with descriptions of some new species.

Cyclopodia horsfieldi, a new species of Nycteribiidæ from Java, J. C. H. De Meijere (*Tijdschr. Ent., 42 (1899), No. 3, pp. 153–157, fig. 1*).—A description and notes on the habits of this species which was found on *Pteropus edulis*.

Ephestia kuehniella V. Mayet (*Prog. Agr. et Vit. (Éd. L'Est), 21 (1900), No. 1, pp. 30, 31*).—Brief notes on the habits and life history of and remedies against this insect.

Heliothis armigera (*Rpt. Govt. Gardens and Parks in Mysore, 1897–98, pp. 17–20*).—A list of plants which are attacked by this insect, with recommendation of well-known remedies.

Revision of the Lathridiidæ of boreal America, H. C. Fall (*Trans. Amer. Ent. Soc., 26 (1899), No. 2, pp. 101–190, pls. 3*).—A monograph of this family of beetles, with notes on the habits of the various species.

Lecanium viride and its extermination, H. Potel (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 8, pp. 464–468*).—A description of the insect, with an account of its habits and life history, and brief notes on remedies for its control.

A new species of plant louse injurious to violets, T. Pergande (*Canad. Ent., 32 (1900), No. 2, pp. 29, 30*).—Describes as new, under the name *Rhopalosiphum violæ*, a species of plant louse which is quite generally distributed in the United States and Canada, and which attacks violets, especially in greenhouses.

The purslane sawfly (Schizocerus zabriskei), F. M. Webster and C. W. Mally (*Canad. Ent., 32 (1900), No. 2, pp. 51–54, figs. 3*).—The eggs are deposited on the edge of the leaves of the common purslane. The insects pupate in the soil at a depth of about 1 in. The entire life cycle occupies about 3 weeks, and there are probably 6 generations in a year. This sawfly is parasitized by a species of Ichneutes.

A plum-tree disease Prillieux and Delacroix (*Bul. Mens. Soc. Cent. Agr. Hort. et Acclim. [Nice], 39 (1899), No. 12, pp. 215, 216*).—A description of the work of Scolytid beetles.

Sitotroga cerealella, V. Mayet (*Prog. Agr. et Vit., 16 (1899), No. 53, pp. 773–777*).—A description of the insect is given, with an account of its geographical distribution. The remedies which are recommended by the author are the application of heat and the use of a machine through which the grain is passed and in which the insect is said to be killed by a mechanical shock. The machine can be operated by two men and consists essentially of a cylinder within a cylinder, both furnished with metallic projections upon their opposing surfaces in such a manner that when the machine is in motion, the grain and insects are subjected to repeated mechanical shocks.

Tortrix ambiguella and means of combating it, J. Perraud (*Prog. Agr. et Vit. (Éd. L'Est), 21 (1900), No. 2, pp. 40–42, pl. 1*).—Brief notes on the habits of this insect and remedies to be applied against it.

FOODS—ANIMAL PRODUCTION.

The proteids of wheat flour, H. SNYDER (*Minnesota Sta. Bul. 63, pp. 519–533*).—The author gives a somewhat exhaustive review of the subject of the chemistry of wheat proteids, and reports a study of the proteids of a number of samples of wheat flour and other milling products. The principal conclusions follow:

> "In the milling of wheat a partial mechanical separation of the various proteids takes place. The germ proteids are composed largely of albumin and globulin bodies, while the bran and shorts contain only about 50 per cent of the total nitrogen in the form of gliadin and glutenin. The removal of the bran shorts and germ from the flour in the process of milling results in an increase in the gliadin-glutenin content of the flour, the nongluten proteids being removed mainly in the offal products.
>
> "In the patent flour from soft winter wheat 73.90 per cent of the total nitrogen was in the form of gliadin, while in the patent flour made from hard winter wheat an average of 63.68 per cent of the total nitrogen was in the form of gliadin. The sticky character of the dough of the soft wheat was probably due to an excess of gliadin, and a deficient amount of glutenin. A well-balanced gluten is composed approximately of 65 per cent gliadin and 35 per cent glutenin.
>
> "The gliadin-glutenin ratio in the different grades of flour made from the same wheat varies from 25 to 75 in the Red Dog, to 65 to 35 in the highest patent. The lower grades of flour contain appreciably more protein than the higher grades, but the gliadin and glutenin in the lower grades are not present in the right proportion to form a well-balanced gluten, capable of expansion, and able to produce bread of the best physical properties."

Physical properties of nuts, C. P. FOX (*Agr. Education, 2 (1899), No. 1, pp. 17–19*).—The author reports a number of physical determinations made with different nuts in the laboratory of W. R. Lazenby of the University of Ohio. These include the number of nuts to the pound, the percentage of kernel to shell, and loss of nuts in cracking. The comparative money value of nuts was also tested. Filberts and peanuts gave the largest number of nuts to the pound. The percentage of kernel to whole nut was highest in the American chestnut and lowest in large hickory nuts. The loss in cracking nuts was found to be about 4 per cent, one half of this being kernel. "If we lay aside the peculiarities of individual taste and consider the matter from a true financial basis, we find that shellbark hickory nuts at 2 cts. a pound and walnuts at 1 ct. a pound are the cheapest. Of the true commercial nuts the peanut at 5½ cts. a pound is the most economical.

Lemon flavoring extract and its substitutes, A. S. MITCHELL (*Jour. Amer. Chem. Soc., 21 (1899), No. 12, pp. 1132–1137*).—The author examined a number of samples of lemon flavoring extract in the course of work for the Wisconsin Dairy and Food Commission. The methods followed are described in some detail.

> "A preliminary examination of the extracts supplied by grocers showed them to contain alcohol in amounts varying from 14 to 94 per cent by weight and oil of lemon from 0 to 8 per cent.
>
> "The extracts low in alcohol had in many cases a fine aroma derived from agita-

tion with new oil of lemon in some cases but more frequently produced by citral and the so-called 'soluble oil of lemon,' or from lemon-grass or citronella aldehyde and frequently with the addition of tincture of nutmeg, mace, or capsicum. The cheaper grades contained so little oil in solution that the addition of water frequently failed to produce turbidity."

Forage plants, fodders, and feeding stuffs, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 112–151*).—The composition is reported of hay from a number of native grasses from "uplands and low lands" in Manitoba and the Northwest Territories, timothy and brome grass hay, soy-bean forage, oat shorts, oat dust, oat-meal dust, oat screenings, molasses refuse or sirup, and cocoa shells, the latter analysis including fertilizer constituents. The hay from the native grasses and sedges included *Carex aristata* and *C. stricta; Deyeuxia neglecta* and *Carex stricta*, 1:1; *Carex straminea; Poa pratensis, P. serotina*, and *Phleum pratense; Deyeuxia confinis* and *Hordeum jubatum; Festuca (Fluminia) arundinacea* (white top); *Festuca scabrella, Agropyron glaucum*, and *A. caninum; A. glaucum, A. caninum*, etc., and weeds; and *Sporobolus cuspidatus*. The composition of a number of these follows:

Composition of hay from Manitoba and the Northwest Territories.

Name.	Water	Protein.	Fat.	Nitrogen-free extract	Fiber.	Ash	Albuminoids.
	Per cent	*Per cent.*	*Per cent*	*Per cent*	*Per cent.*	*Per cent.*	*Per cent*
Deyeuxia neglecta and *Carex stricta*, 1:1	6.28	10.00	3.52	45.49	28.30	6.41	10.62
Carex straminea	6.38	7.06	2.51	49.41	29.52	5.12	7.50
Festuca (Fluminia) arundinacea (white top)	7.20	6.75	2.24	43.61	34.18	6.02	7.25
Deyeuxia confinis	6.65	7.00	2.75	41.52	35.88	6.20	7.50
Carex aristata	6.95	9.00	3.10	47.27	26.03	7.65	9.69
Sporobolus cuspidatus	6.33	5.94	2.82	49.39	28.62	6.90	6.31

The comparative value of upland and lowland hay is discussed.

The two samples of molasses refuse examined had the following composition:

Composition of molasses refuse.

	Water.	Protein	Nitrogen-free extract.	Cane sugar.	Glucose	Ash.
	Per cent.	*Per cent*	*Per cent.*	*Per cent.*	*Per cent*	*Per cent.*
Sample No. 1	24.89	7.81	5.98	50.27	1.95	9.10
Sample No. 2	26.42	6.85	3.10	50.05	5.00	8.58

This crude sirup cost ¾ ct. per pound and, in the author's opinion, should prove a profitable feeding stuff. It is stated that from 2 to 4 lbs. can be fed per head daily economically and safely.

Digestion experiments with sheep, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1898, pp. 204–220*).—Continuing the work of previous years, a number of digestion experiments with sheep are reported.

The usual methods were followed. A summary of the experiments is given in the table below:

Coefficients of digestibility—experiments with sheep.

	Organic matter.	Protein.	Fat.	Nitrogen-free extract.	Fiber.	Ash.	Available energy.
	Per cent	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent*	*Per cent.*	*Per cent.*
Sweet corn fodder (green), average of two sheep	69.4	60.3	70.3	73.7	62.9	58.3	65.7
Oat and pea fodder (green), average of two sheep	58.3	69.2	56.0	62.2	48.6	37.3	54.1
Soy bean fodder (green), average of four sheep	66.8	[illegible].2	36.0	78.6	44.3	....	60.4
Sweet corn fodder (green), average of two sheep	76.0	[illegible]3.2	69.2	81.8	38.9	31.6	71.9
Barley and pea fodder (green); average of two sheep	71.2	74.5	58.5	75.5	61.2	53.7	65.2
Barley fodder (green), average of two sheep	68.2	68.7	49.1	74.0	55.9	41.8	62.2
Fine rowen hay, average of four sheep	64.6	72.5	45.2	62.3	65.7	45.9	58.3
Fine rowen hay and Cleveland flax meal, average of three sheep	67.9	78.8	53.4	60.4	69.6	37.0	59.0
Fine rowen hay and Quaker oat feed, average of three sheep	61.3	68.5	56.3	62.8	55.6	34.7	58.4

The results of these and earlier digestion experiments at the station are summarized.

On the digestion of milk, R. W. RAUDNITZ (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, No. 1–2, pp. 53–59*).—Cats were fed sterilized whole milk; milk and water; fat milk, *i. e.*, a mixture of cream, skim milk, and water; milk and water containing sodium carbonate, pancreatin, and a mixture of the two; and milk and water containing hydrochloric acid. Two or three hours after the food was given the cats were killed and the stomach contents analyzed. Among the conclusions drawn were the following: Milk diluted with water leaves the stomach more quickly than whole milk. Of two samples of milk containing the same amount of fat but different percentages of nitrogen, that containing the least nitrogen leaves the stomach sooner. The values obtained show, according to the author, that resorption in the small intestine does not keep pace with the passage of food from the stomach. Neither sodium carbonate, pancreatin, or hydrochloric acid or a mixture of sodium carbonate and pancreatin hastened the passage of milk from the stomach.

Live stock at the Central Experimental Farm, W. SAUNDERS (*Canada Expt. Farms Rpts. 1898, pp. 73–88*).—Statistics are given of the horses, cattle, swine, poultry, and bees kept at the Central Experimental Farm, and feeding experiments with steers and swine are reported.

Experiments in the feeding of steers, 1897–98 (pp. 74–86).—Tests with 11 lots of 2 steers each were made with a view to learning "how beef can be produced at the smallest cost, how such products as the farmer can easily grow can be used to the best advantage, and what results are had where rations are fed the nutritive ratio of which is wider than is usually recommended."

In all cases except lot 9 the test covered 16 weeks and was divided into 4 periods of 4 weeks each. Lots 1, 2, 5, 6, 7, 8, and 11 were fed a coarse fodder consisting of silage, turnips, cut hay, and cut straw. Lots 3 and 4 were fed silage hay, and straw; lot 9, timothy hay and turnips; lot 10, brome-grass hay and turnips. In addition the animals were fed bran, cotton-seed meal, oil meal, and mixed meal, consisting of equal parts of peas, barley, and oats. The steers were given all the coarse fodder they would eat up clean, were watered twice daily, and supplied with salt. The amount of grain fed differed in the different experiments but in general was increased as the test progressed. Lots 1 to 4, inclusive, were not given meal until the second period. The nutritive ratio of the rations varied but was in no case lower than 1:7.7 in the first period and 1:5.2 in the last period. The results of the test are summarized in the following table:

Results of feeding steers.

	Average weight at beginning	Total gain per steer	Cost of food per pound of gain		Average weight at beginning	Total gain per steer.	Cost of food per pound of gain.
	Pounds	*Pounds*	*Cents*		*Pounds*	*Pounds*	*Cents.*
Lot 1	850	155 5	4 22	Lot 7	952 5	216 5	6.53
Lot 2	977 5	188	4.61	Lot 8	877 5	199 5	5 74
Lot 3	965	140 5	6 59	Lot 9	940	188	6 75
Lot 4	867 5	163 5	4 81	Lot 10	882 5	122 5	7.81
Lot 5	852 5	169 5	6 58	Lot 11	695	198 5	4 96
Lot 6	972 5	218	5 75				

The best results were obtained, in the author's opinion, with lots 1, 2, 4, and 11. The experiments are not discussed in detail.

Experiments in fattening swine (pp. 86–88).—The value of feeding whole and ground grain, dry and soaked, as well as the value of a mixture of soaked ground grain and clover, was tested with 5 lots of 4 crossbred swine each. Lot 1 was fed a mixture of unground oats, barley and peas and bran, 2:2:2:1. Lot 2 was fed the same mixture soaked in cold water for 30 hours. Lot 3 was fed the same mixture ground and dry; lot 4, ground and soaked in cold water; and lot 5, the same grain ration with sufficient cut clover to make a mixture of 3 parts of meal to 1 of clover by weight. The mixed meal and clover were soaked in cold water on an average for 30 hours. The test began July 20, 1898, and covered 14 weeks. The pigs were fed all they would eat up clean. The following table summarizes the results:

Results of feeding swine.

	Total weight at beginning	Total gain per lot.	Food consumed per pound of gain.		Total weight at beginning.	Total gain per lot.	Food consumed per pound of gain.
	Pounds.	*Pounds.*	*Pounds.*		*Pounds*	*Pounds*	*Pounds.*
Lot 1	270	432	4 08	Lot 4	266	496	3.76
Lot 2	263	422	3 88	Lot 5	273	274	*a* 4.80
Lot 3	275	505	3.56				

a This includes 3 6 lbs meal and 1 2 lbs. clover.

No conclusions are drawn from the tests.

Experiments in feeding steers, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1898, pp. 300, 301*).—The value of marsh hay as compared with mixed straw was tested with 2 lots of 4 steers each. Lot 1 was fed a ration consisting of 20 lbs. of cut native marsh-grass hay, 30 lbs. Swedish turnips, and 3 to 7 lbs. of chopped barley, while lot 2 was fed 20 lbs. of mixed cut straw, the same amount of Swedish turnips as lot 1, and 5 to 9 lbs. of chopped barley. The steers were fed for 112 days. They were purchased for 3 cents per pound and sold at the conclusion of the test for 4 cents per pound, live weight. The financial statement is based on hay at $5 per ton, turnips at 5 cents per bushel, and chopped barley at half a cent a pound. No value was assigned to the straw.

Lot 1 made an average daily gain of 1 lb. 6 oz., and lot 2, 1 lb. 4 oz. The average profit per steer for lot 1 was $7.54; of lot 2, $10.91. "It would appear that hay is not essential to the successful fattening of steers, and that wheat farmers can utilize to good advantage a portion of their straw for that purpose."

Experiments in the feeding of steers, A. MACKAY (*Canada Expt. Farms Rpts. 1898, pp. 369, 370*).—A feeding test with steers at the Indian Head Experimental Farm is briefly reported. Twelve 3-year-old steers were divided into 4 lots of 3 each and fed from November 13, 1897, to March 5, 1898. Lot 1 was given brome-grass hay and silage; lot 2, wheat chaff and silage; lot 3, threshed brome grass, silage, and bran; and lot 4, native hay, silage, and bran. In addition all the steers were fed 2 lbs. of meal (barley and wheat 2:1) per head daily during the second month, 4 lbs. during the third, and 6 lbs. during the last month of the test. "The rations were in the proportion of 2 lbs. silage to each pound of dry feed." The financial statement is based on silage at $2, brome-grass hay at $5, threshed brome grass hay at $4, native hay at $2, bran at $14, and wheat chaff at $2 per ton, and meal at $\frac{5}{8}$ ct. per pound.

The total gains made by the several lots were as follows: Lot 1, 430 lbs.; lot 2, 315; lot 3, 355; lot 4, 460. The profits on the respective lots were $27.39, $29.04, $34.09, and $44.65.

Report on experiments on the winter fattening of cattle, 1898–99, J. W. PATERSON (*West of Scotland Agr. Col. Bul. 1, pp. 22*).—To determine the comparative value of a number of concentrated feeding stuffs, a test beginning December 24, 1898, and covering 100 days, was made at the Home Farm of H. Ogilvy at Biel, with crossbred steers selected from a herd of 80. During a preliminary period of one month, the steers were divided into 2 uniform lots, and at its conclusion were subdivided into 4 uniform lots of 10 each. Lots 1, 2, and 3 were fed a basal ration of 560 lbs. of Swedish turnips with oat hay and straw *ad libitum*. In addition, lot 1 was fed 60 lbs. of decorticated cotton-seed cake and maize meal (1:1); lot 2, 60 lbs. of linseed cake; lot 3, 60 lbs. of decorticated cotton-seed cake and bruised oats (1:1), Lot 4 was fed a basal ration of 840 lbs. of Swedish turnips with oat hay and straw *ad libitum*, and 30 lbs. of decorticated cotton-seed cake in addition. During the last 17 days of the test, the amount of grain fed to lots 1, 2, and 3 was increased to 80 lbs. At the same time the Swedish turnips fed to lot 4 were increased to 933 lbs. and the grain ration to 40 lbs.

The weights of the 4 lots at the beginning of the test were 8,059, 7.824, 7,908, and 8,115 lbs., respectively. The corresponding daily gains per head were 2.23, 2.35, 2.25, and 1.99 lbs., respectively. The feeding stuffs were rated as follows: Linseed cake, $39.60 per ton; decorticated cotton-seed cake, $29.66; maize meal, $25.25; Swedish turnips, $2.40; straw, $7.25; hay, $14.55; and oats, 54 cts. per bushel. Rating the steers at $6.72 per cwt. at the beginning of the test and $8.16 per cwt. at the close of the test, and assuming the attendance was worth 12 cts. per head per week, the profit on the 4 lots was $69.25, $40.15, $60.96, and $57.18, respectively.

In the author's opinion, the gains made by all the lots were very satisfactory, slightly the best being made by lot 2. The increase during the last 17 days of the test was said to be satisfactory for all the lots, and in the author's opinion the feeding might have been advantageously continued for some time.

> "Linseed cake produced rather more increase than decorticated cotton-seed cake plus oats, but this increase did not repay the extra expense. Indeed, there was a relative loss of $20.84 from preferring linseed cake. When contrasted with the cotton-seed cake plus maize lot, the employment of pure linseed cake was still more unprofitable. Decorticated cotton-seed cake plus maize yielded exactly $29 10 more profit than linseed cake—the extra gain being all a saving in expenditure. These results merit the attention of feeders. . . . In a season of root scarcity, the advisability of limiting the turnips, as in lot 1, and giving maize instead will be specially apparent. Again, looking to lots 3 and 4, when turnips are worth $2.40 per ton to sell it will pay better to restrict them as in lot 3 and give some oats instead when oats are selling below 59 cts. per bushel of 40 lbs., or $4.72 per quarter. As the same amount of Swedish turnips and practically the same quantity of hay and straw was consumed by the first 3 lots, the relative results arrived at above for the concentrated foods are obviously in no way influenced by the fixed prices which were placed upon those foods."

Feeding experiments on the winter fattening of lambs, C. E. LYMAN, reported by C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1898, pp. 221–228*).—In these experiments, which are made with the cooperation of C. E. Lyman of Middlefield, who feeds each winter about 4,000 lambs for market, the fattening value of wide and narrow rations was compared, 2 lots of 10 lambs each (mostly selected grade Shropshires) being used for the purpose. The test, which began December 21, covered 2 periods of 31 days each. Lot 1 was fed at first a ration consisting of ⅔ pea meal and ⅓ corn, with about 1 part of clover rowen to 2 parts of corn silage. After about 10 days bran was substituted for part of the pea meal, since it was evident satisfactory gains could not be made otherwise. Until the close of the test the grain ration consisted of pea meal, bran, and corn, 2 : 1 : 1, giving a nutritive ratio of 1 : 7.2. The grain ration of lot 2 consisted of corn and pea meal, 3 : 1. The coarse fodder in the first period consisted of corn silage and clover rowen 2 : 1. During the second period the clover rowen was increased ½. The nutritive ratio of the ration was 1 : 6.8. The lambs in lot 1 weighed 882, those in lot 2, 869 lbs. at the beginning of the test; the total gains during the test were 242 and 281 lbs., respectively. The cost of a pound of gain in lot 1 was 4.93 and in lot 2, 4.77 cts.

> "It will be seen that the gains for the second lot, which were fed the wide rations, are considerably larger than for the first lot, which had the narrow ration. The wide ration (lot 2) was somewhat more expensive than the narrow ration (lot 1), but the average cost of 100 lbs. of increase was 16 cts. less for the lambs fed the wide ration."

A test was also made with 200 lambs, which were fed well-balanced rations found by experience to be profitable. The test proper began December 1, 1897, and covered 3 periods of 15, 16, and 17 days. In the first period the ration consisted of 167 lbs. each of corn and pea meal, 148 lbs. of clover rowen, and 325 lbs. of silage. In the second period the clover rowen and silage remained about the same, while the corn meal was increased to 181, the pea meal diminished to 138, and 9 lbs. of bran was added to the ration. In the third period, the 196 lambs were fed 132 lbs. of corn, 100 lbs of bran, the same quantity of pea meal daily with about the same amount of clover rowen and silage as before. The nutritive ratio in the 3 periods was 1:5.8, 1:6.1, and 1:5.6, respectively. The lambs were purchased in Chicago. A few days after their arrival in Connecticut they were sheared and yielded 3⅜ lbs. of medium wool per lamb, on an average. Near the end of the test it was necessary to slaughter 4 lambs and this fact is taken into account in tabulating the results for the third period.

At the beginning of the test the lambs weighed on an average 73½ lbs. each. During period 1 the total gain of the lot was 1,140 lbs., and the cost of a pound of gain 4.58 cts.; during the second period the total gain was 690 lbs., and the cost of a pound of gain 7.91 cts.; while during the third period the total gain was 1,230 lbs. and the cost of a pound of gain 4.85 cts. The cost is based upon hay at $10, silage at $3. bran at $15, and pea meal at $13 per ton, and corn at 38½ cts. per bushel.

> "The ration which in the long run has given us the most satisfactory results in feeding lambs is one very similar to that used in the third period with the large lot of lambs. A grain ration consisting of one-third corn, one-third bran, and one-third pea meal by weight, together with coarse fodder consisting of clover hay or clover rowen one part, and corn silage two parts, has, on the whole given us very satisfactory returns."

Pig feeding in South Dakota, E. A. BURNETT (*South Dakota Sta. Bul. 63, pp. 85-98*).—Two tests are reported which had for their object a comparison of some of the common feeding stuffs, and the collection of data regarding the cost of pork production from common grains under favorable conditions.

The first test was made with 30 pure-bred Duroc Jersey, Chester White, and Poland China pigs, divided into 6 lots of 5 each. The pigs were from 130 to 160 days old, and averaged about 114 lbs. each. During the summer they had been pastured on a variety of crops, and were given some ground barley shorts and separator skim milk. The test began October 21 and covered 4 periods of 2 weeks each. Lot 1 was fed corn meal; lot 2, wheat shorts; lot 3, corn meal and shorts (1:1); lot 4, barley meal with wheat shorts (1:1); lot 5, corn meal and ground barley; and lot 6, ground barley. Each lot received a little soft coal and salt, with a little copperas and sulphur occasionally.

The average weights of the 5 lots at the beginning of the test were 801, 775, 723, 746, 711, and 726 lbs., respectively. The average daily gains of lots 1, 2, and 6 were 1.53 lbs., 4.53, and 4.38, and 4.58 lbs. of food was required per pound of grain respectively. The average daily gains of lots 3, 4, and 5 were 1.8, 1.64, and 1.44 lbs., respectively. The corresponding amounts of food required per pound of gain were 3.9, 4.29, and 4.86 lbs.

The second test was made in 1898 with 7 lots of 4 pigs each, and was practically a duplicate of the previous test. The lots were numbered from 7 to 13 consecutively. Lots 13, 11, 10, and 12 were fed, respectively, the same ration as lots 2, 3, 5, and 6, while lots 7, 8, and 9 were fed the same ration as lot 4 in the previous test. After a preliminary period, during which the pigs were pastured on barley and oats or rape and sorghum, the test proper began September 26 and covered 4 periods of 14 days each. The following table summarizes the results:

Results of feeding pigs—second experiment.

	Weight of lot at beginning of test	Average daily gain	Food consumed per lb of gain		Average daily gain	Weight of lot at beginning of test	Food consumed per lb of gain
	Pounds	*Pounds*	*Pounds*		*Pounds*	*Pounds*	*Pounds*
Lot 7	612	1 56	4 77	Lot 11	589	1 50	4 48
Lot 8	692	1 76	4 82	Lot 12	592	1 67	4 56
Lot 9	514	1 58	4 40	Lot 13	591	1 31	5 17
Lot 10	614	1 65	4 51				

In discussing the profits of the 2 experiments, the different grains are figured at $8 per ton. Lots 1–6 were valued at $3.10 at the beginning and end of the test, a shrinkage of 4 per cent being made on the weight of the pigs at the close of the test, which was the average shrinkage on the lot when purchased. Lots 7–13 inclusive were purchased at $3 per hundred and sold at the same price without shrinkage. The cost per pound of gain in the different lots was as follows: Lot 1, 1.81 cts.; lots 2 and 13, 1.88 cts.; lots 3 and 11, 1.6 cts.; lots 4, 7, 8, and 9, 1.82 cts.; lots 5 and 10, 1.9 cts.; lots 6 and 12, 1.83 cts. The author calculates that corn meal returned in the form of pork, $13.60 per ton;

wheat shorts, $13.20 per ton; corn meal and wheat shorts (1:1), $15.46 per ton; barley and shorts (1:1), $13.70; barley and corn (1:1), $12.04; and barley, $13.60.

The experiments are discussed in considerable detail. The principal conclusions follow: "All foods and rations used in the experiment produced gains at a cost considerably below the market price of hogs at the time they were fed. All lots made the cheapest gains before reaching 150 lbs. weight, but continued to make profitable gains up to or slightly past 200 lbs. weight. The largest consumers of food according to weight made the cheapest gains. Corn and shorts made the cheapest gains, and all the rations containing corn gave better average results than all the rations containing no corn."

Feeding experiments with blood molasses feed for horses, H. GOLDSCHMIDT (*Landmandsblade, 32 (1899), No. 25, pp. 349–353*).—Twenty three horses belonging to the Copenhagen Milk Supply Company were included in the experiment. They were divided into 2 lots. Lot 1, made up of 7 horses, was fed the regular ration of barley and oats, 1:2, during the first part of the test; later, oats and hay. Lot 2, made up of 16 horses, received the same feed with the following changes during the 3 periods into which the experiment was divided: In period 1, 2 lbs. of molasses feed was substituted for 2 lbs. of grain; in period 2, 2½ lbs. of molasses feed was substituted for 3 lbs. of grain; and in period 3, 3 lbs. of molasses feed took the place of 4 lbs. of grain. The amount of grain fed during the different periods ranged from 10½ lbs. to 12 lbs. and from 12 to 13 lbs. of hay was fed per head per day. The results obtained show that 3 lbs. of molasses feed had about the same feeding value as 4 lbs. of grain. At the prevailing prices, the molasses feed was cheaper than grain; by replacing ¼ of the grain with this feed, an annual saving of $5.36 per horse would be effected, while in the case of high prices for oats, the saving would reach $13.40 per horse annually.—F. W. WOLL.

Report of the poultry manager, A. G. GILBERT (*Canada Expt. Farms Rpts. 1898, pp. 221–240, pl. 1, figs. 5*).—Statistics are given of the poultry kept at the station during the past year, methods of feeding them, comparative egg yield for 2 years, eggs set, chickens and ducks hatched, gain in weight of chickens, etc.

Experimental fattening of chickens without forced methods, (pp. 234–240).—The relative merits for fattening without forced methods of scrubs, first cross, and thoroughbred chickens were tested with 10 lots of 4 chickens each made up as follows: Lots 1 and 2, barnyard chickens; lot 3, first cross light Brahma-Buff Cochins; lot 4, light Brahmas; lot 5, Silver Laced Wyandottes; lot 6, White Indian Game and White Java cross; lot 7, Barred Plymouth Rocks; lot 8, White Plymouth Rocks; and lot 9, White Wyandottes. The lots were fed 3 times a day all they could eat of oatmeal, barley, and corn meal, 2:1:1, mixed with sweet milk. About 2 weeks after the beginning of the test beef suet (1 ounce to each 4 fowls) was also fed each meal. The chickens were given grit and an abundance of water. Two of the chickens were pullets; the remainder, cockerels. The test began October 31 and covered 8 weeks. During this period 1 chicken in lot 4 died and 1 each in lots 5 and 9 was not in good condition for a portion of the time. The foods consumed and gains made per week by the different chickens and lots are recorded in detail. At the close of the test the chickens were fasted for 36 hours previous to killing. They were killed by dislocating the neck, and carefully plucked dry and packed for shipment. The weight after fasting 36 hours in lots 4 to 9, and in all cases the weights after plucking, are recorded. The weight of the entrails, of the waste, heads, feet, etc., weight after dressing, weight of the giblets, fat, flesh, bones, and extractives obtained on boiling are recorded for 1 chicken in each lot. The results of the test are summarized in the following table:

Results of feeding experiments with chickens.

	Average weight per chicken.										Weight of entrails, head, feet, etc *a*	Weight of parts. *a*				
	At beginning of test.		At end of test.		After 36 hours' fast.		After plucking.		After dressing *a*			Giblets.	Fat.	Flesh.	Bone.	Extractives obtained by boiling.
	Lbs.	*Ozs*	*Lbs.*	*Ozs*	*Lbs.*	*Ozs.*	*Lbs.*	*Ozs*	*Lbs*	*Ozs.*	*Ozs*	*Ozs*	*Ozs*	*Ozs*	*Ozs.*	*Ozs.*
Lot 1...	4	12½	6	2	....		5	9½	4	1	20½	4	8½	44	10½	4
Lot 2 ..	3	9	5	2	....		4	9½	3	1½	18	4	2	39	8	3
Lot 3...	6	5	8	4½	....		7	10½	5	7	28½	5	5	54½	13	5
Lot 4...	6	2½	6	3	6	1	5	9½	4	8½	28	5½	5	50	11	4½
Lot 5 ..	5	0	6	5	5	14½	5	12	3	7½	18	4	4	39	10	4
Lot 6...	4	2½	5	12½	5	10½	5	6	3	12½	17½	4	7	32	7½	3
Lot 7 ..	5	15	7	8½	7	6½	6	15	4	8	25	4½	2	46	11½	6
Lot 8...	5	11	7	6½	7	4	6	12½	4	11	26	5½	3½	49	10½	5
Lot 9 ..	4	6	6	1½	5	11	5	4	4	2	21	5	4½	44	12	4

a These values were determined with a representative chicken from each lot.

Poultry, S. A. BEDFORD (*Canada Expt. Farms Rpts. 1898, pp. 302, 303*).—The value of pullets compared with old hens as layers was tested with 2 lots of 11 chickens each. Lot 1 was made up of 7 Black Minorca and 4 White Plymouth Rock hens 2½ to 4 years old, and lot 2 of the same number of pullets of these 2 breeds, 6 months old. All the chickens were fed in the morning a ration of equal parts of crushed mixed grains and 1 oz. of cut bone per fowl. The food was moistened. In the evening they were fed whole wheat, oats, and barley 2:1:1. From January 4 to March 4 the pullets laid 144 eggs and the hens 105.

The value of bone as an egg producer was tested with 2 lots each consisting of 3 Plymouth Rock and 3 Black Minorca pullets 6 months old. Both lots were fed on bran and crushed mixed grain 1:1, wet, in the morning, and wheat screenings, oats, and barley 2:1:1 in the evening. In addition, lot 1 was fed an ounce of green bone per chicken daily in the morning. In the 3 months beginning January 4 lot 1 laid 83 and lot 2, 52 eggs.

The cost of a pound of gain when chickens are fattened in pens was tested with 4 Plymouth Rocks. In one month beginning October 25 they consumed 7½ lbs. of wheat, 3¾ lbs. of oats, and the same amount of barley. The grain was crushed and fed moist in the morning and whole in the evening. The chickens weighed 16 lbs. 14 oz. at the beginning of the test and gained 5 lbs. The cost of a pound of gain was 3 cts.

Concerning "slimy" bread, R. SENDTNER (*Chem. Ztg.*, *23* (*1899*), *No. 79, p. 827*).

Canadian and Hungarian flours, F. T. SHUTT (*Canada Expt. Farms Rpts. 1898, pp. 153, 154*).—An analysis is reported of "Best Patent" and of Hungarian flour.

Composition of meat conserves, PELLERIN (*Jour. Pharm. et Chim., 6. ser., 9* (*1899*), *No. 10, pp. 20–25; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 3* (*1900*), *No. 1, p. 32*).—The author reports the examination and analysis of bouillon from canned meat.

The digestibility of sterilized milk, JEMMA (*Clin. Med. Italiana; abs. in Diet. and Hyg. Gaz., 16* (*1900*), *No. 2, p. 83*).—The author reports, as the result of experiments in artificial digestion, that the digestibility of milk is not impaired by sterilizing, and that sterilized milk diluted with a solution of milk sugar is more easily digested than pure sterilized milk.

Contribution to the study of the composition of hens' eggs, A. JUCKENACK (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2* (*1899*), *No. 12, pp. 905–913*).—The author studied especially cholesterin and other phosphorus compounds in egg yolk.

Preserving eggs (*Queensland Agr. Jour., 4* (*1899*), *No. 3, pp. 418, 419*).—Several methods of preserving eggs are quoted—as preserving in a water glass solution, preserving with a solution of salt and borax poured over eggs covered with vegetable ashes, and packing in some material (bran, salt, etc.) in tight boxes.

Apple jelly, LOOK (*Ztschr. Offentl. Chem., 5* (*1899*), *pp 359–366; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 2* (*1899*), *No. 12, pp. 934, 935*).—Analyses of a number of sorts of commercial jelly are reported.

The composition of raisins, A. BORNTRAGER (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2* (*1899*), *No. 3, pp. 257–260*).—The composition of a number of samples is reported.

Recent progress in regard to wines and food stuffs, E. LIST (*Chem. Ztg., 23* (*1899*), *No. 74, pp. 757–759; No. 76, pp. 784–788*).—A review.

Muscle, brain, and diet: A plea for simpler foods, E. H. MILES (*London: Swan, Sonnenschein & Co.; New York: The Macmillan Co., 1900, pp. XV+345*).—The author believes a diet of what he terms simpler foods, *i. e.*, a "vegetarian diet," is desirable. His own experience and considerable other data are recorded, which he believes supports his contentions. The book is prepared from a popular rather than a scientific standpoint.

The army ration, C. SMART (*Sanitarian, 44* (*1900*), *No. 363, pp. 125–129*).—In this article, quoted from the Boston Medical and Surgical Journal, December 9, 1899, the author describes the army ration and discusses its value for soldiers in the tropics. Attention is drawn to the fact that the ration is capable of considerable variation to suit special circumstances.

The army ration in the tropics, P. R. EAGAN (*Sanitarian, 44* (*1900*), *No. 363, pp. 129, 130*).—A brief note supplementing the above article.

Analyses of fodders and feeding stuffs, W. O. ATWATER and F. G. BENEDICT (*Connecticut Storrs Sta. Rpt. 1898, pp. 229–242*).—The composition of a number of materials is reported. These include green fodders—*Bromus inermis*, meadow fescue, orchard grass, redtop, timothy, cowpea fodder, barley and pea fodder, barley fodder, oat and pea fodder, soy bean fodder, sweet corn fodder, and corn for silage; cured fodders and hay—corn stover, clover rowen, mixed hay of clover and grass, Hungarian hay, hay of mixed grasses, fine rowen hay, and second quality hay. In addition, several samples of corn silage were analyzed. The milling and by-products include Chicago gluten meal, Cleveland flax meal, cotton-seed meal, Quaker oat feed, wheat bran, soy beans, and four o'clock seed. [According to a correspondent in Florida four o'clock seed is a very satisfactory feed for poultry.]

Analyses of foods, feeding stuffs, etc., H. SNYDER (*Minnesota Sta. Bul. 63, pp. 495–503, 505–508*).—Analyses are reported of linseed oil meal, foreign and domestic flaxseed (oil content), oat bran, oat feed, wheat screenings, speltz wheat, corncobs, wild rice, corn (yellow and white), cattle-feed mixtures, rape plant at different stages of growth, corn fodder, oat hay, pea hay, dwarf German kale, sand vetch, sorghum, peas and oats, *Bromus inermis*, sugar, sorghum, sirup, butter, dairy salt, skim milk, and 2 food preservatives.

The feeding value of the residue from wine making (*Bul. Soc. Cent Agr. Hort. et Acclim.* [*Nice*], *39* (*1899*), *No. 8, pp. 145–149*).

The use of cane leaves in feeding cattle, BONÂME (*Sucr. Indig., 54* (*1899*), *No. 18, pp. 550–553*).

Artificial milk or Liebig milk for calves and young pigs, F. RIGAUX (*Belg. Hort. et Agr., 11* (*1899*), *No. 17, p. 265*).—A note on the use of a mixture of flour, malt, carbonate of potash, and a little chalk in skim milk for calves and young pigs.

The formation of fat from protein according to the latest opinion of the C. Voit school, E. PFLÜGER (*Arch. Physiol.* [*Pflüger*], *77* (*1899*), *No. 11–12, pp. 521–554*) —A controversial article.

Concerning the absorption of fat, W. CONNSTEIN (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, No. 1–2, pp. 30–32*).—Experiments were made with dogs fed lanolin in addition to a ration of dog biscuit. This fat melts at 40 to 42° C. and is easily emulsified. It saponifies with great difficulty in the intestine and is practically unabsorbed. Therefore, in the author's opinion, the conclusion is warranted that the digestibility of any fat depends upon its cleavage, and that its capacity for emulsification is only a secondary matter.

Report of the poultry division, D. D. HYDE (*New Zealand Dept. Agr. Rpt. 1899, pp. 153–161, figs. 11*).—The different breeds of chickens and ducks are described and the work of the poultry department briefly reported.

A handbook for farmers and dairymen, F. W. WOLL (*New York: John Wiley & Sons, 1900, pp. 437*).—A second edition of this book containing a large amount of information in condensed form over a wide range of subjects. The edition is said to be thoroughly revised.

DAIRY FARMING—DAIRYING.

Dairy experiments, C. B. LANE (*New Jersey Stas. Bul. 137, pp. 24*).—The record of a grade dairy herd for 3 years is summarized and discussed, and experiments comparing balanced and unbalanced rations and different quantities of feed are reported.

The yield, composition, and cost of milk (pp. 3–12).—The grade dairy herd used in a study of this question averaged annually 22, 25, and 30 cows for the years ended April 1, 1897, 1898, and 1899. The records for 1897 and 1898 were given at some length in the annual reports of the stations for those years (E. S. R., 10, p. 483; 11, p. 785). Frequent changes were made in the herd by replacing older and unprofitable animals by new ones. Four cows remained in the herd for the 3 years and 10 others remained for 2 years. Of 25 cows for which a record of one year or more was obtained the annual milk production of the best, poorest, and average cow was, respectively, 10,317, 4,530, and 6,585 lbs., with a corresponding butter production of 486, 226, and 327 lbs. The fat content of the milk of the individual cows for 1 year ranged from 2.8 to 6.4 per cent, with an average of 4.25 per cent.

During the summer the ration fed consisted of 60 lbs. of green forage, 4 lbs. each of wheat bran and dried brewers' grains, and 2 lbs. of corn meal, and during the winter of 30 lbs. of silage, 5 lbs. of hay, 4 lbs. each of bran and brewers' grains, and 2 lbs. of linseed meal. The average cost of the ration was 11.5 cts., 5 cts. being charged to purchased feeding stuffs and 6.5 cts. to farm crops. The cost of food for 1 year was $1,049.38. Labor and interest on the value of the herd increased the total cost of milk production to $1,651.88. The total yield of milk was 75,511 qt., the cost per quart being, therefore, 1.39 cts. for food, or 2.19 cts. for food, labor, and interest. At 3 cts. per quart for milk the net profit from the 25 cows, not including the value of 265 tons of manure, was $613.45. The increased cost of producing milk according to sanitary requirements is discussed in connection with these results.

A study was made of the question of maintaining a standard of quality in herd milk throughout the year. A table shows the average composition of herd milk and the variation in composition of the milk of individual cows for each month during the 3 years. "Milk containing 4 per cent of fat could have been practically guaranteed throughout the first year, 4.25 per cent the second, and 4.50 per cent the third."

Experiments with different rations (pp. 12–24).—A ration made up of 30 lbs. of silage, 5 lbs. of timothy hay, 4 lbs. of wheat bran, 4 lbs. of dried brewers' grains, and 2 lbs. of linseed meal was compared with one composed of 12 lbs. of cornstalks, 8 lbs. of timothy hay, and 4 lbs. of corn meal. The nutritive ratio of ration 1 was 1:5.3 and of ration 2, 1:13.5. The rations were fed to 2 lots of 2 cows each for 30 days, when they were reversed, and after a transition period of 7 days were fed for another period of 30 days. A table gives the daily record of each cow. The total production on the first ration was 2,701.7 lbs. of milk and 131 lbs. of butter, and on the second ration 2,014.2 lbs. of milk and 94.3 lbs. of butter, making an actual gain in production of over one-third in favor of the balanced ration. The cost of food for the production of 100 lbs. of milk and 1 lb. of butter was practically the same in each case. It is therefore argued that 20 cows fed the balanced ration would produce as much milk at the same cost for food as 30 cows fed the other ration, the profits being much greater with the smaller number of cows on account of less labor and a smaller investment being required.

A summary is given of tests of 3 grade cows for 1 week and comment is made on the value of records for short periods.

Several tests, lasting 1 week each, were made with 2 cows to determine the profits from feeding different quantities of mixed grains. Rations consisting of 10, 15, 20, and 24 lbs. of the same proportional mixture of wheat bran, dried brewers' grains, and linseed meal were fed with silage and hay. The results are given in tables and discussed. "Rations containing feeds in excess of 10 lbs. per day, while they were profitable, were less profitable than those containing this amount."

Experiment with milch cows, R. ROBERTSON (*Canada Expt. Farms Rpts. 1898, pp. 258–261*).—A study was made of the profits from a herd of 29 cows for one year ended November 27, 1898. The cows were charged with all the feed consumed and given credit for their products at current prices. A table shows the breed, number of days milked, yield of milk and butter, receipts from butter and skim milk, cost of feed, and other data for each cow. Excluding one cow which had been milked 210 days before entering the test, and 3 cows which were removed from the test at the end of 6 months, the profits per cow ranged from $4.10 to $28.64, and averaged $16.25. The results are averaged separately for the summer and winter periods of 6 months each. Cows fresh in the fall were more profitable than cows fresh in the spring.

Test of malt-sprouts-molasses for milch cows, E. RAMM (*Milch Ztg., 28 (1899), No. 41, pp. 611, 642*).—In a series of feeding experiments with milch cows conducted by the author a comparative test was made of malt-sprouts molasses and peanut cake. From April 4 to April 7, 8 cows were fed peanut cake in addition to hay, straw, roots, and dried brewers' grains. During a second period of 4 days beginning April 13, the cows were fed the same ration except that the peanut cake was replaced by the same quantity of malt-sprouts-molasses. From April 26 to April 29 the cows were fed again on the peanut-cake ration. The data are given in full in tabular form. A summary of the results for 5 cows shows that the yield of milk was slightly higher on the peanut ration, but the fat content was lower, so that the average daily yields of fat and total solids were practically the same on the two rations. The author concludes that malt-sprouts molasses proved an efficient and wholesome concentrated feeding stuff for milch cows, and under the conditions of the experiments was equal in value to peanut meal.

Test of gluten meal for milch cows, E. RAMM (*Milch Ztg., 28 (1899), No. 12, pp. 658–660*).—A comparative test of gluten meal and peanut cake was made with 5 cows and included 3 periods of 4 days each, beginning respectively on May 5, 14, and 23. During the first and third periods the daily ration included 6 kg. of peanut cake. During the second period an equal quantity of gluten meal was fed in place of the peanut cake. The results are tabulated and summarized. The yields of milk, fat, and total solids and the specific gravity of the milk were slightly higher on the gluten-meal ration, but the percentages of fat and solids were lower. The experiment is considered as showing that gluten meal is a very efficient feeding stuff for milch cows.

Test of raw sugar for milch cows, E. RAMM (*Milch Ztg., 28 (1899), No. 43, pp. 673, 674*).—In continuation of the above experiment raw sugar was compared with peanut cake. A ration containing 6 kg. of raw sugar was fed to 5 cows for 4 days commencing June 4, and the results are compared with the average results obtained from feeding a ration containing peanut cake in place of the sugar to the same cows for two periods of 4 days each, commencing respectively May 23 and June 13. The results are tabulated and summarized. On the sugar ration the cows gained more in weight but produced less milk and butter fat than on the peanut ration.

Changes in milk caused by freezing, M. SIEGFELD (*Molk. Ztg., 13 (1899), No. 32, pp. 497–499*).—Several experiments in freezing milk and cream are reported and changes in the microscopical appearance of the fat globules and in the properties of the casein as a result of freezing are described.

Analyses were made of samples from different portions of a block of frozen milk. The upper portion of the block contained 8.45 per cent of fat and the lower portion 2.11 per cent. The percentage of total solids increased toward the center of the cake.

To eliminate the influence of the fat an experiment was made with skim milk. The outer portion of the frozen sample contained 7.03 per cent of solids and the central part 15.9 per cent. Another sample of the skim milk was kept at 5–6° C. for 8 hours. Ice crystals were formed in the outer portion. Analyses of the ice, the serum mechanically held by the ice crystals, and the central portion of the sample remaining unfrozen, gave the following percentages of solids for the 3 portions, respectively: 0.06, 9.94, and 12.81. The fresh sample contained 8.32 per cent of solids and 0.07 per cent of fat.

In 2 experiments one half of each lot of cream was frozen. In the first experiment the 2 portions were brought to 16° C. and churned at that temperature. In the second experiment the churning was done at 13°. The freezing of the cream resulted in decreasing the time required for churning 13 minutes in the first case and 15 minutes in the second. The content of fat in the buttermilk from the unfrozen cream churned at 16 and 13° was respectively 5 and 4.8 per cent, and from the cream which had previously been frozen, 2.95 and 1.55 per cent. A number of other experiments confirmed these results.

Some practical applications of bacteriology in European dairying, H. W. CONN (*Connecticut Storrs Sta. Rpt. 1898, pp. 67–99*).—This is an interesting account of the conditions found by the author as the result of an examination of various institutions in England, Holland, Denmark, Germany, and Switzerland. The subject is discussed under 3 general headings, (1) bacteriology and the milk supply in European cities, (2) bacteriology in butter making in European dairies, and (3) bacteriology in cheese making in Europe. A summary regarding the more important practical applications of bacteriology to dairying in Europe is given as follows:

"(1) A knowledge of the action of bacteria upon milk has led to a very careful guarding of milk from contamination. This has been directed first to the cow, second to the conditions in the cow stall, third to the cleaning of the milk vessels, and fourth to the methods of handling the milk.

"(2) The demonstration of the agency of milk in distributing disease has led to the taking of great pains to prevent the milk from coming in the vicinity of disease germs. This has resulted in (1) the attempt to exclude all persons who have contact with contagious diseases from any participation in handling the milk; (2) greater care in regard to the water used in the dairy; and (3) the attempt to exclude from the dairy herd all animals suffering from any sort of udder disease.

"(3) Proper regulations can be better enforced by large business firms than by public statute, and partly as a result of this the milk supply of the large cities is passing into the hands of a few large firms.

"(4) As the public has learned how disease is distributed by milk the demand for sterilized milk has grown until it can be purchased in most cities from the ordinary milkmen. The dislike of the taste of sterilized milk and the belief that sterilizing makes it somewhat less easily digested have led to the adoption of the process of pasteurizing, though it is rather slow in coming into use.

"(5) The use of bacteria cultures for cream ripening in the process of butter making is confined chiefly to Denmark and North Germany. In Denmark over 95 per cent of the butter is made by the use of artificial pure cultures of bacteria inoculated into pasteurized cream. The results have been highly satisfactory to the Danish butter makers. Oleomargarine is largely made by the use of pure cultures.

"(6) Up to the present no important practical applications of bacteriological knowledge have been made in the process of cheese making. The only instance in practice where bacteria are artificially inoculated into milk to produce cheese ripening is in the use of 'slimy whey' in the making of Holland cheeses."

Examinat'on of butter and milk for tubercle bacilli, ASCHER (*Ztschr. Hyg. u. Infectionskrank., 32 (1899), No. 3, pp. 329–344*).—Twenty-seven samples of butter from 22 stores were examined and 2 samples were found to contain tubercle bacilli. One came from a large creamery and the other from an estate. A sample of skim milk from the creamery also showed tubercle bacilli. This skim milk was being used to feed calves and pigs. The author believes the pasteurizing of skim milk and centrifugal slime at cooperative creameries before returning it to patrons should be compulsory. The milk of 7 cows which had reacted with tuberculin but showed no clinical evidence of tuberculosis was repeatedly tested for bacilli by inoculating guinea pigs, with entirely negative results.

Trials of pasteurization apparatus, 1897–1899, H. P. LUNDE and P. V. F. PETERSEN (*43. Rpt. K. Vet. Landbohöjskoles Lab. Landökon. Forsög [Copenhagen], 1899, pp. 152, ill.*).—This is an account of a critical investigation of 5 different forms of Danish pasteurization apparatus, 3 of which are modifications of the original Fjord pasteurizer. The various factors affecting the efficiency of pasteurizers were studied in detail; a new modification of the Fjord apparatus suggested by the results of the investigations was constructed and is described and illustrated in the report. Tables showing the effect on the efficiency of pasteurizers of the temperature and the heat-conductivity of the heating surface are given, and formulas for their calculation presented, as well as other factors that determine the efficiency of pasteurizers. Among the results obtained may be mentioned that a pasteurization apparatus under otherwise similar conditions will be found to possess only between one-half and one-third as large a capacity when the milk (or cream) is to be heated to 85° C. (185° F.) as when it is heated to 70° C. (158° F.).—F. W. WOLL.

How to select good dairy cows, E. RIGAUX (*Ind. Lait*, *25* (*1900*), *Nos. 2, pp. 9–11; 3, pp. 17–19; 4, pp. 25, 26*).—The principal breeds of dairy cattle are enumerated and the conformation of the dairy cow is discussed.

Modern dairying, D. WILSON and R. CROWE (*Melbourne: Dept. Agr. Victoria, 1898, pp. 66*).—This is intended for an "up-to-date manual" for dairymen in Victoria.

Malt-sprouts-molasses as a feeding stuff for milch cows (*Milch Ztg.*, *28* (*1899*), *No. 37, pp. 595–597*).—In a feeding experiment with 6 cows covering about 6 weeks, a mixture of malt sprouts and molasses was of practically the same value as roots and wheat bran. The material used consisted of malt sprouts, 47.5 per cent, and molasses, 52.5 per cent, and had been kept in storage without an indication of molding or other deterioration for 8 months previous to the experiment. Its use as a substitute for roots and bran is considered dependent solely upon the cost.

Influence of food on the composition of butter, A. RUFFIN (*Ind. Lait.*, *25* (*1900*), *No. 1, pp. 1, 2*).—Determinations of the index of refraction, saponification number, and volatile acids of samples of butter made from cows fed cotton-seed cake, peanut cake, and cocoanut cake alone and in combination with forage are considered as showing some variations in the composition of butter due to the different feeding stuffs.

Complete reports on investigations of the milk of 63 Dutch cows bred in East Prussia during one or more periods of lactation (*Gesamtberichte über die Untersuchung der Milch von dreiundsechzig Kühen des in Ostpreussen rein gezüchteten holländischen Schlages während der Dauer einer oder mehrerer Laktationen. Berlin: Paul Parey, 1899, pp. 551; abs. in Milch Ztg.*, *28* (*1899*), *No. 39, pp. 617, 618*).

Tests of dairy herds in Silesia, B. SCHULZE (*Milch Ztg.*, *28* (*1899*), *No. 35, pp. 549, 550*).—Results of tests of 12 cows for 4 months and of 48 cows for 1 year are given.

Tests of milch cows in Algau (*Milch Ztg.*, *28* (*1899*), *No. 47, pp. 740–743*).

Observations on dairying, A. J. MCCLATCHIE (*Arizona Sta. Rpt. 1899, pp. 259, 260*).—A summary account is given of tests of several dairy herds.

Composition of Holland butter, W. G. INDEMANS (*Ind. Lait.*, *24* (*1899*), *No. 39, p. 310*).—This is a brief summary of determinations during 1898 of the volatile fatty acids of 600 samples of butter with reference to seasonal variations. A table shows the maximum, minimum, and average Reichert number for the samples analyzed each month. No general deductions are drawn.

Necessity of reforms in dairying, B. PLEHN (*Milch Ztg.*, *28* (*1899*), *No. 42, pp. 660, 661*).—A discussion of the production and sale of milk in Germany according to sanitary requirements.

The adulteration of butter, MARSAC (*Ind. Lait.*, *24* (*1899*), *No. 39, pp. 309, 310*).—The author reviews experimental work by several investigators testing the sesame oil reaction for the detection of margarin in butter.

Adulteration of milk and butter in Germany (*Ind. Lait.*, *24* (*1899*), *No. 45, p. 358*).—This is a brief review of a report on this subject from the Institute of Hygiene at Hamburg. Variations in the composition of milk and butter are discussed in connection with legal standards. A case is noted where the removal of cows from a clover pasture in October followed by feeding a mixture of peanut cake, wheat bran, and ground oats and barley resulted in the production of butter having an abnormally low content of volatile fatty acids. The sesame oil reaction for the detection of margarin in butter is not considered wholly conclusive.

Cynarase, a new diastase which coagulates milk, G. E. RASETTI (*Abs. in Ann. Agron.*, *25* (*1899*), *No. 12, p. 620*).—A description of a ferment prepared from the flowers of the wild artichoke (*Cynara cardunculus*), and used in Italy for making a kind of cheese from sheep's milk. It is said to be superior for this purpose to rennet, giving properties to the cheese which are much prized. The properties and preparation of the ferment are described.

"Germ-free" milk for feeding infants and for general use, F. SIEGERT (*München. Med. Wchnschr., 46 (1899), p. 1533; abs. in Chem. Ztg., 23 (1899), No. 96, Repert., p. 354*).—Forster's method, by which the less resistant pathogenic micro-organisms in milk are killed, is used in a commercial way in Strasburg. The milk is produced under as cleanly conditions as possible and placed at once in liter flasks closed with rubber stoppers and heated for 25 to 30 minutes in a water bath at 65° C. The cost of this operation is said to be about 2 pfennigs (0.5 ct.) per bottle of 900 cc. contents.

Investigations on the virulence of milk of tuberculous cows, DOUGLAS (*Abs. in Ztschr. Medizinalbeamte, 12 (1899), No. 22, p. 750; and Ztschr. Fleisch u. Milchhyg., 10 (1899), No 3, p. 53*).—In these experiments, made by an English medical officer, 8 cows out of 15 examined were found to have udder tuberculosis. With the milk of these 8 cows 48 experiments were made, 34 of which showed a transmission of tuberculosis. In 69 experiments with the milk of tuberculous cows, in none of which the udder was affected, the disease was not transmitted in a single case.

Creaming, C. H. WATERHOUSE (*Agr. Education, 2 (1899), No. 2, pp. 30, 31*).—A popular discussion of different methods.

On an improved process for renovating butter, H. SCHROTT (*Milch Ztg., 28 (1899), No. 40, pp. 630, 631*).

Bacteriology in practical cheese making in Europe, H. W. CONN (*Amer. Cheesemaker, 14 (1900), No. 167, pp. 1, 2*).

Problems in cheese making, G. A. SMITH (*Amer. Cheesemaker, 14 (1900), No. 167, pp. 4, 5*).—A popular discussion of the qualifications of cheese makers and the cheese-producing power of different milks.

VETERINARY SCIENCE AND PRACTICE.

Report of the veterinary department, W. C. LANGDON (*North Dakota Sta. Rpt. 1898, pp. 29–32*).—This report contains an account of experiments which were made for the purpose of testing the value of mallein and creolin in the treatment of glanders. Horses which were suffering from glanders were given weekly injections of 1 cc. of mallein and were given 1 dr. of creolin in ½ pt. of water 3 times daily. Beside the creolin received by way of the mouth, the horses were also given a daily rectal injection of this substance in a 1 per cent solution of water. After this treatment had been conducted for 3 weeks, the horses gave clinical symptoms of the bad effects of creolin. In order to overcome its depressing action the horses were given pulverized digitalis leaves and pulverized nux vomica with sulphate of iron. The dose of creolin was then increased to 2 dr. 3 times a day. This treatment was continued for 5 weeks, at which time all clinical symptoms of glanders had disappeared. Later the treatment was discontinued and the horses were put to work. At the close of the season one of the horses was killed and a *post-mortem* examination revealed no living germs of glanders. Two horses were inoculated with pure cultures of the glanders bacillus and then treated in the manner just outlined. Only one of these horses has been destroyed, and in this case the *post-mortem* failed to develop any evidence of glanders bacillus in the living condition.

Intravenous injection of anthrax bacillus in sheep which have been strongly immunized against anthrax and the interaction of the specific antitoxin and the bacillus, A. SCLAVO (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 14-15, pp. 425-431*).—The simultaneous injection of protective serum and a culture of anthrax bacillus produced an elevation of temperature. After a second inoculation of the bacillus there was only a slight temperature reaction or none at all. Protective substances could not be demonstrated in the blood serum of these sheep until some time after the sheep were themselves able to resist the anthrax bacillus. The author's experiments indicated that repeated inoculation of the bacillus would eventually overcome the resistance of the organism. In explanation of this condition it is suggested that the protective substances do not operate directly against the bacillus, but indirectly through the medium of the leucocytes.

The present attitude of European science toward tuberculosis in cattle, H. W. CONN (*Connecticut Storrs Sta. Rpt. 1898, pp. 11-66*).—This paper contains a general discussion of the opinions of European veterinarians and agriculturists upon the various problems connected with tuberculosis in cattle.

Tuberculous cows and the use of their milk in feeding calves, C. S. PHELPS (*Connecticut Storrs Sta. Rpt. 1898, pp. 100-112*).—Four cows which responded to the tuberculin test were selected for the experiment, for the reason that tuberculosis seemed to be present in them in its earlier stages. The purpose of the experiment was to study "the effect of the milk of slightly diseased cows when fed to healthy calves, and also the relative danger from the spread of the disease by association with diseased animals." The cows were tested at intervals by the college veterinarian. Three months after beginning the experiment the cows were tested and all 4 responded to the test. Three months later they were tested again and only 2 responded. The next test occurred about 4 months later, when none of the cows gave any response to the test.

Detailed records are given of the results of feeding the calves upon the milk of these cows. The calves were also tested with tuberculin. The results of the experiments may perhaps be best stated in the author's own words:

> "Bovine tuberculosis is usually a disease of slow development, its progress depending quite largely upon the general vigor of the animal and its power to resist the action of the germs. In nearly 2½ years that the tuberculous cows have been at the station, only 1 secondary case has appeared, and this was discovered about 6 months after the feeding period with milk had ended.
>
> "In the experiments here reported, 8 calves have been fed upon the milk of tuberculous cows for periods varying from 3 months to 16 months without developing the disease.
>
> "The results of these experiments coincide with the general results of European

observations, and indicate that the danger from the spread of tuberculosis through the milk of cows to man or to other animals is not as great as has generally been supposed. In the earlier stages of the disease and at all times when the udder is not affected, the danger from the use of the milk is quite limited. Great stress, however, should be laid on the danger of using milk from cows which show any symptoms of udder affection."

Louping ill and the grass tick, E. G. WHELER (*Jour. Roy. Agr. Soc England, 3. ser., 10 (1899), pt. 4, pp. 626–644, figs. 7*).—This paper is occupied for the most part with an account of a study of the habits and life history of the grass tick (*Ixodes reduvius*). Detailed descriptions are given of the egg, larva, pupa, adult male, and adult female. The eggs probably are laid at the roots of coarse herbage. The larvæ are 6-legged. They climb upon the stems of grasses in a manner similar to that of other related ticks, and are thus brushed off upon passing animals. After fully distending themselves with blood, they fall to the ground, where they remain for a varying length of time, depending upon climatic and other conditions. During this period the molting takes place, and the ticks pass into the pupal stage. In this condition they again attach themselves to animals, and after becoming filled with blood, again drop to the ground, where a second molting occurs. The adults again attach themselves to animals, and the females, after being distended with blood, drop to the ground and deposit their eggs. The number of eggs deposited by a single female is large, varying from about 2,000 to 15,000.

According to the author's observations, the ticks fast during the periods when they are upon the ground. It is probable that no nourishment of any sort is taken during these periods. It was shown by experiments that the ticks could live for nearly a year without any nourishment, provided they were protected against desiccation. In a dry atmosphere, or exposed to the sun, they died within two or three days.

The time required for the completion of the life cycle varies exceedingly, and depends upon the temperature and a number of other natural conditions. The variation in time may be from 1 to 3 years. It is possible for the tick to complete the life cycle in slightly less than a year, provided the temperature is favorable and the tick is successful in securing a host readily. The grass tick is known to attack a considerable variety of animals, including cattle, horses, deer, sheep, and often men and dogs. Only cattle and sheep, however, are found to acquire louping ill from the attack of the tick.

Wherever coarse herbage abounds, and a moderate amount of moisture is present, the ticks are enabled to pass their resting stages successfully upon the ground. If, on the other hand, the grass is short, and the ticks are therefore exposed to the direct rays of the sun, they can not tide over these resting periods between the different stages, and if they drop upon such ground they perish. Some pastures are known to be free from louping ill, and this condition may be accounted for in the way just indicated. In order to exterminate the tick, it is not sufficient to dip the sheep and thus kill the ticks which may be at the time upon the sheep. Those ticks which at the time were upon the ground will escape and will be in position to infect sheep which are brought upon the premises. The author recommends as measures for the destruction of the ticks the burning and cutting of long grasses, rushes, etc.; the removal of diseased sheep to a separate inclosure, where handpicking of ticks and dipping may be performed; giving salt and sulphur to infected sheep; and the slaughter and burial of all infected sheep. Inoculation for the purpose of producing immunity has been tried with some success, and better results are to be hoped for in this line.

A method for the differential diagnosis of the bacillus of Eberth and the coli bacillus, L. A. Silberberg (*Russk. Arch. Patol. Klin. Med. i Bakt., 8 (1899), No. 2, pp. 152–156*).—These two bacilli may be distinguished by differences in their reaction to arsenious acid.

Successful treatment of tetanus with bromid of soda, chloral hydrate, and pilocarpin, Aryazhev (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 12, II pp. 561–568*).—Observations upon a number of cases of tetanus in which these substances were used.

Changes in the properties of the blood of animals which have been injected with the blood or serum of another species of animal in relation to Ehrlich's theory of immunity, F. Y. Chistovich (*Russk. Arch. Patol. Klin. Med. i Bakt., 8 (1899), No. 1, pp. 21–37*).—Results were obtained which tend to confirm the observations of Wassermann and Ehrlich on the preexistance of antitoxines in normal cells. The literature of the subject is discussed in connection with a bibliography.

The problem of serum therapy, J. Danysz (*Przegl. Weterynarski, 14 (1899), No. 4, pp. 97–107*).—An experimental study of the effect of the bile and blood serum of diseased animals when injected into healthy animals.

Preventive and curative sera derived from animals which have been immunized against hog cholera, K. Z. Kleptzov (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 11, II, pp. 501–509*).—A discussion of experiments conducted by the author upon hog cholera

Investigations on the toxicity of normal emulsified tissues when injected into the animal organism by the intravenous method, D. J. Mut (*Gac. Méd. Vét., Madrid, 24 (1900), No. 15, pp. 3–11*).—Emulsions of cerebral pulmonary or hepatic tissue injected into the veins produced cardiac paralysis. The same emulsions when boiled were inactive. Emulsions of the muscular tissue and of the spleen, kidney, thyroid gland, and suprarenal capsule were inactive. A repetition of doses of emulsions from active organs produced immunity against their action.

The reaction of the animal organism toward the blood serum of other animals, H. Friedenthal and M. Lewandowsky (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. 1, pp. 531–543*).—The general results of the authors' study may be briefly summarized as follows: The blood sera of the different sexes do not differ from each other in any respect. The serum of one species, when injected into the blood of another species, produces poisonous effects of varying degrees of intensity. Upon heating the serum for a considerable time to a temperature of 60° C., its poisonous principle is destroyed.

Intravenous injections, P. Chaussée (*Rec. Méd. Vét., Paris, 8. ser., 6 (1899), No. 23, pp. 721–734*).—Experiments with antitetanic and antistreptococcic sera. The author concludes that the intravenous method has the following advantages: The immediate and complete diffusion of the serum through the body, a less dilution of the serum, and the avoidance of the ordinary complications of abscess.

Incubation period of contagious diseases of animals and nullification of the

sale in such cases, V. Galtier (*Jour. Méd. Vét. et Zootech., 5. ser., 3 (1899), pp. 697-703*).—A discussion of the periods of incubation in different diseases as affecting the sale of animals in which contagious diseases develop after being sold and removed to new quarters.

The question of governmental regulation of the inoculation of animals with preventive vaccines, N. Dikovski (*Vyestnik Obsh. Vet., 10 (1898), No. 12, pp. 447-450*).

Disinfection by means of formaldehyde after the occurrence of infectious diseases, M. T. Meshchadimenko (*Russk. Arch. Patol. Klin. Med. i Bakt., 8 (1899), No. 1, pp. 37-51, fig. 1*).—A detailed account of experiments in the use of formaldehyde gas for disinfection purposes, during which the action of this gas upon a number of pathogenic organisms was studied. A bibliography of the literature of the subject is added to the article.

Phototherapy, S. S. Evsyeenko (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 7, II, pp. 221-230*).—A discussion of the practical value of the application of X-rays in veterinary practice.

The illumination of stables for domestic animals and its influence upon diseases of the eye, Tomarov (*Arch. Vet. Nauk, St. Petersburg, 29 (1899), No. 11, pp. 552-555*).—Animals which are being fattened should be kept in more dimly lighted quarters than animals which are to be used for work purposes.

Contagious diseases of animals, A. G. Hopkins (*Rpt. Farmers' Inst. Manitoba 1899, pp. 8-10*).—Notes on a number of the more common animal diseases.

Cattle plague, I. Gordzyalkovski (*Vyestnik Obsh. Vet., 11 (1899), No. 9, pp. 390-396*).—A discussion of the symptoms and etiology of the disease, with an account of experiments with bile and blood serum in producing immunity.

The present scourge of cattle raising, Y. Polferov (*Vyestnik Obsh. Vet., 10 (1898), No. 9, pp. 327-329*).—A discussion of the cattle plague.

Concerning actinomycosis, Preusse (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. 1, pp. 255-273, figs. 3*).—A discussion of the nature and prevalence of this disease in animals, with an account of the frequency of human infection.

The history of the development of actinomyces in pus of cattle, D. Korsak (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 1, II, pp. 20-24, pls. 2*).—A detailed account of the different stages in the development of this organism, many of which are figured.

The bacteriology of anthrax, N. N. Mari and S. L. Schensnovich (*Russk. Arch. Patol. Klin. Med. i Bakt., 7 (1899), No. 5, pp. 490-493*).—A report upon a technical study of the anthrax bacillus with reference to its growth upon various culture media.

The biology and method of contagion of anthrax, P. N. Andreev (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 10, II, pp. 395-418; No. 11, II, pp. 443-480; No. 12, II, pp. 513-553*).

Plasmolysis in the anthrax bacillus in relation to the question of the cell wall of bacteria and the brownian movement, V. V. Podvuisotzki and V. A. Taranukhin (*Russk. Arch. Patol. Klin. Med. i Bakt., 5 (1898), No. 6, pp. 653-662, pl. 1*).—A technical bacteriological study.

The influence of different conditions upon the increased virulence or attenuation of virulent anthrax cultures and anthrax vaccines in relation to their action upon living animals which have been inoculated with them, I. N. Kovalevski (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 7, II, pp. 255-281*).—An elaborate study of the influence of temperature and other conditions of increasing or diminishing the virulence of anthrax cultures, together with clinical notes upon the effects of such cultures upon animals.

The influence of lecithin and of organic substances which contain lecithin on the biology of the anthrax bacillus, V. A. Taranukhin (*Russk. Arch. Patol. Klin. Med. i Bakt., 6 (1898), No. 1, pp. 1-3*).—Lecithin was found to have a decidedly stimulating effect on the growth of the anthrax bacillus.

The diagnosis of anthrax, ARNDT (*Berlin. Tierärztl. Wchnschr., 1899, No. 52, pp. 624–628*).—A detailed discussion of the symptoms of anthrax and of those diseases with which it might be confused.

Further proof of the action of creolin against anthrax, HANSEN (*Berlin. Tierärztl. Wchnschr., 1899, No. 49, p. 591*).—An outbreak of anthrax was treated with creolin, 30 grains being given as a dose at first. Later another dose of 20 grains was given. Several cases were treated in this way with complete recovery as the result.

The problem of the disinfection of the soil in case of anthrax, A. E. TYURMORYEZOV (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 6, II, pp. 177–185*).—A report upon extensive experiments undertaken for the purpose of determining the most practical and effective method of destroying the organism of anthrax within the soil.

The importance of tuberculin in the diagnosis of tuberculosis, D. VAN DER SLUIJS (*Tijdschr. Veeartsenijk en Veeteelt, 26 (1898), No. 1, pp. 19–26*).—An experimental investigation of the reaction to tuberculin.

The use of the flesh of tuberculous animals, D. A. DE JONG (*Jour. Comp. Path. and Ther., 12 (1899), No. 4, pp. 315–325*).—Recommends the inspection of animals intended for food, and the condemnation of all cases of acute miliary tuberculosis and cases in which tuberculous lesions are present in the muscular tissue or its lymphatic glands. Condemned meat and condemned organs should be sterilized provided the commercial value of the meat after sterilization is not less than the cost of the process.

Cattle, A. MACKAY (*Canada Expt. Farms Rpts. 1898, pp. 368, 369*).—Statistics are given of the cattle kept at the Indian Head Experimental Farm as well as of the tests made in the herd for tuberculosis. Of 52 animals tested only 2 reacted.

Long persistence of the bacillus of Koch in the nasal passages of the guinea pig, P. VIOLLET (*Compt. Rend. Soc. Biol. Paris, 11. ser., 1 (1899), No. 39, pp. 996–998*).—The tubercle bacillus may live almost indefinitely upon the mucus membranes of the nose.

Hematuria of cattle, O. MAKAROV (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 10, II, pp. 137–142*).—A discussion of the symptoms of this disease, together with observations upon the effects of various drugs in controlling them.

Toxæmic hemoglobinuria of cattle, I. KACHINSKI (*Vyestnik Obsh. Vet., 11 (1899), No. 13, pp. 564–569*).—An experimental study of the symptoms and etiology of this disease.

Preventive inoculation for epizootic pneumonia, G. KOTLUBAI (*Vyestnik Obsh. Vet., 11 (1899), No. 16, pp. 677–681*).—Excellent results are reported from this treatment.

The organism of epizootic pleuro-pneumonia of cattle, NOCARD and ROUX (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 5, II, pp. 139–155*).—A detailed record of experimental work on this disease.

Parturient apoplexy of cows, L. IVANOV (*Arch. Vet. Nauk., St. Petersburg, 29 (1899), No. 11, pp. 561–564*).—An account of the symptoms etiology, and course of the disease. Treatment with potassium iodid is recommended.

Prophylaxis of lungworm disease, T. KASPAREK (*Arch. Wiss. u. Prakt. Thierh., 26 (1900), No. 1, pp. 70–73*).—An outbreak of the disease among calves was studied, and it was found that in order to prevent the spread of the disease, it was necessary to disinfect the stalls and destroy the old wood in such places.

Effects on cattle of eating macrozamia roots, J. H. MAIDEN (*Agr. Gaz. New South Wales, 10 (1899), No. 12, p. 1259*).—This plant is greedily eaten by cattle and is said to produce "rickets."

Dehorning cattle, F. GILLANDERS (*New Zealand Dept. Agr. Rpt. 1899, p. 170. pls. 2*).—The method of dehorning cattle at the Momohaki Experiment Station is described.

Sarcosporidiasis among buffalo (*Arch. Vet. Nauk., St. Petersburg, 28 (1898), No. 9, II, pp. 357–368*).—An account of the Sporozoa which live parasitically in buffaloes, including the genera Miescheria, Carcocystis, and Balbiania.

Sheep scab (*Jour. Bd. Agr.* [*London*], *6* (*1899*), *No. 3, pp. 346–349, figs. 2*).—Notes on *Psoroptes communis* and *Melophagus ovinus*.

Treatment of sheep scab, V. GRIGOREV (*Vystnik Obsh. Vet.*, *11* (*1899*), *No. 1, pp. 6, 7*).—Recommends for hand treatment a remedy containing corrosive sublimate, alcohol, oil of terebinth, and pine tar.

The transportation of wool from sheep which have been affected with sheep pox, V. AMELIN (*Vyestnik Obsh. Vet.*, *11* (*1899*), *No. 18, pp. 765–767*).—A discussion of the danger of spreading the disease in this manner.

Vaccination against sheep pox, V. AMELIN (*Vyestnik Obsh. Vet.*, *11* (*1899*), *Nos. 11, pp. 477–481*; *12, pp. 525–528*).—A detailed account of experiments conducted in the prevention of sheep pox by serum inoculation.

Hemaglobinemia of sheep, LE BLANC and SAVIGNÉ (*Jour. Med. Vet. et Zootech.*, *5. ser.*, *3* (*1899*), *pp. 703–710*).—This is a report of an experimental study of the disease in sheep. The pathogenic organism is apparently carried from animal to animal by means of insects. Santonin or sulphate of quinin and subcutaneous injections of methylene blue gave good results as treatment for the disease.

Epizootic pneumonia in goats, V. MATVYEEV (*Uchen. Zapiski Kazan. Vet. Inst.*, *15* (*1898*), *No. 5–6, pp. 315–324*).—A study of the symptoms, etiology, and treatment of pneumonia in goats.

Epizootic diseases of the reindeer, N. I. EKKERT (*Arch. Vet. Nauk, St. Petersburg*, *28* (*1898*), *Nos. 1, III, pp. 1–31; 2, III, pp. 51–99*).—An elaborate account of the diseases which are known to affect reindeer, with a discussion of the literature of the subject and a bibliography.

The transmission of hog cholera to man, CASPER (*Deut. Thierärztl. Wchnschr.*, *7* (*1899*), *No. 50, pp. 445, 446*).—A description of the symptoms and course of the disease in four cases.

Hog cholera, K. Z. KLEPTZOV (*Arch. Vet. Nauk.*, *St. Petersburg*, *28* (*1898*), *No. 1, II, pp. 10–20*).—An account of serotherapy in this disease.

Inoculation against hog cholera with the Landsberg serum, SCHREIBER (*Berlin. Tierärztl. Wchnschr.*, *1899*, *No. 51, pp. 611–613*).

The use of "Susserin" in hog cholera, M. CASPER (*Deut. Thierärztl. Wchnschr.*, *7* (*1899*), *No. 51, pp. 453–456*).—This remedy, having been tested by inoculation of more than 60,000 hogs, is reported to be cheap and effective.

An investigation of preventive vaccines for hog cholera, I. GORDZYALKOVSKI (*Vyestnik Obsh. Vet.*, *10* (*1898*), *No. 11, pp. 404–406*).—A statement of the results obtained from a practical application of preventive inoculation.

Hemorrhagic septicæmia (swine plague), N. N. MARI and A. I. AGAREV (*Arch. Vet. Nauk, St. Petersburg*, *28* (*1898*), *No. 1, II, pp. 1–10*).—An experimental study of swine plague, with observations upon guinea pigs which were inoculated with the disease.

Morphology of bacillus mallei, A. KRAEVSKI (*Vyestnik Obsh. Vet.*, *11* (*1899*), *No. 8, pp. 341–345*).—A bacteriological investigation, with a discussion of the relationship of the glanders bacillus to other organisms.

The natural recovery of horses from glanders, V. M. SULIN (*Arch. Vet. Nauk, St. Petersburg*, *28* (*1898*), *No. 4, II, pp. 119–122*).—From careful clinical records kept upon the cases of glanders, this is believed to occur occasionally.

The problem of controlling glanders on the steppes, V. KOLPAKOV (*Vyestnik Obsh. Vet.*, *11* (*1899*), *No. 5, pp. 206–210*).—A record of work done, with an account of the difficulties of the problem.

Epizootics of glanders along the frontiers of the government of Saratov, F. BEREZOV (*Vyestnik Obsh. Vet.*, *10* (*1898*), *Nos. 2, pp. 47–51; 3, pp. 87–91; 4, pp. 127–131*).—A detailed study of several outbreaks of glanders.

Glanders, and sanitary regulations, O. LEBRUN (*Rev. Vet. Toulouse*, *25* (*1900*), *No. 1, pp. 31–33*).—Discusses the danger of human infection by glanders, and recommends the annual inspection of all horses and mules by veterinarians.

Fighting glanders in St. Petersburg and the surrounding country in 1897,

S. Samborski (*Vyestnik Obsh. Vet., 10 (1898), No. 14, pp. 528–530*).—An account of regulations adopted and enforced against glanders.

The diagnostic value of mallein in detecting glanders in horses, I. N. Potapenko (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), Nos. 6, II, pp. 203–219; 7, II, pp. 237–254*).—A critical discussion of the literature of the subject, and a report of observations upon the reliability of mallein as a test for glanders.

Materials for the study of the mallein problem, A. A. Kraevski (*Arch. Vet. Nauk, St. Petersburg, 29 (1899), Nos. 10, pp. 495–516; 11, pp. 519–538.*)—In this article the author presents a historical review of the literature on mallein in connection with a bibliography of 216 titles. Experimental investigations were conducted upon the subject of the reaction of horses to mallein and the factors which modify this reaction.

The problem of the influence of the sex of horses upon their susceptibility to disease, A. Ryazhev (*Arch. Vet. Nauk, St. Petersburg, 29 (1899), No. 11, pp. 539–552*).—A statistical account of the relative frequency of various diseases in geldings and mares. The frequency was found to be greater in the former than in the latter.

The presence of the botfly larvæ in the nasal cavities of horses mistaken for glanders, D. Polyakov (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 5, II, pp. 173–175.*)—A record of the symptoms of a number of cases, with suggestions which help in distinguishing the irritation caused by botfly larvæ from glanders.

Observations on the transmission and treatment of epizootic pleuro-pneumonia of horses, I. N. Potapenko (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 2, II, pp. 25–39*).—An account of the etiology and methods of contagion in this disease.

The diagnosis of periodical iritis of horses, S. A. Gryuner (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 2, II, pp. 47, 48*).—A discussion of the various forms and the etiology of iritis in horses.

Distemper and rabies, D. V. Devel (*Arch. Vet. Nauk, St. Petersburg, 28 (1898), No. 3, II, pp. 65–79*).—A discussion of the difficulties attending a reliable differential diagnosis of these two diseases.

The pathological anatomy and bacteriology of canine distemper, Y. N. Petropavlovski (*Russk. Arch. Patol. Klin. Med. i Bakt., 7 (1899), No. 6, pp. 597–620*).—By means of microscopic examinations it was possible to demonstrate the presence of the specific bacillus of canine distemper in the lungs, liver, spleen, submaxillary glands, mesenterical glands, and in pustules found in the skin.

Hypodermical injections of pure culture of the bacillus in young dogs produced the symptoms of canine distemper. The same result was obtained by inoculation of mice and guinea pigs. The lungs and liver were the first organs to become infested with the bacillus.

The infusoria which live in the stomach of ruminants, W. Kulczycki (*Przegl. Weterynarski, 14 (1899), Nos. 7, pp. 193–197; 8–9, pp. 218–235, figs. 15*).—Detailed notes on the occurrence and physiological or pathological effects in the stomach of ruminants of 12 species of infusoria.

An improved apparatus for hypodermic injection, Carl (*Deut. Tierärztl. Wchnschr., 7 (1899), No. 49, p. 437, figs. 3*).—A description of a needle which is free in a great degree from the disadvantages of the ordinary instrument for this purpose.

AGRICULTURAL ENGINEERING.

The homemade windmills of Nebraska, E. H. Barbour (*Nebraska Sta. Bul. 59, pp. 79, figs. 79*).—This bulletin gives sketches of typical windmills, built by farmers in Nebraska, accompanied by brief descriptions. It is the first of a proposed series of bulletins, the object of which is "to bring together views of a number of mills, and to compile facts about their uses, construction, cost, and durability which may be of possible use to prospective builders, and by which they may be enabled to select the design which seems to them least faulty or best suited to their individual wants."

It is stated that homemade mills are extensively used on the western plains. "They extend in almost unbroken succession from Omaha to Denver, and from South Dakota through Nebraska, Kansas, and Oklahoma," Nebraska being plainly the center of the movement. It is the experience of those using such mills that they are cheap, useful, and durable. The windmills described in this bulletin are classified as jumbo windmills, merry-go-round windmills, and turbine windmills. The bulletin also contains some discussion of uses of shop-made windmills and other water lifters, storage of windmill power, and transmission of windmill power, and gives a list of miscellaneous papers by the author on homemade windmills of Nebraska.

The annual work of a windmill, H. D'ANCHALD (*Jour. Agr. Prat., 1899, II, No. 45, pp. 677, 678*).

STATISTICS—MISCELLANEOUS.

Tenth Annual Report of Arizona Station, 1899 (*Arizona Sta. Rpt. 1899, pp. 225–262, pls. 2*).—This contains the organization list of the station; reports of the director, chemist, botanist, agriculturist and horticulturist, and meteorologist, reviewing the work of the station for the year and including articles noted elsewhere; and a financial statement for the fiscal year ended June 30, 1899.

Eleventh Annual Report of Connecticut Storrs Station, 1898 (*Connecticut Storrs Sta. Rpt. 1898, pp. 248*).—The report contains the board of trustees and officers of the station, a financial statement for the fiscal year ended June 30, 1898, a brief review of station work by the director, and a number of articles abstracted elsewhere.

Eleventh Annual Report of Kansas Station, 1898 (*Kansas Sta. Rpt. 1898, pp. XVII*).—This includes financial reports of the treasurer and secretary for the fiscal year ended June 30, 1898, a summary of Bulletins 76–80 of the station, a brief review of station work in progress, the organization list of the station, and a subject list of previous publications. Reprints of Bulletins 76–80 of the station on the following subjects are appended: Fifth report on Kansas weeds—vegetative propagation of perennial weeds (E. S. R., 10, p. 359), some insects injurious to the orchard (E. S. R., 10, p. 369), sugar beets (E. S. R., 10, p. 346), bovine tuberculosis (E. S. R., 10, p. 395), and sixth report on Kansas weeds—distribution and other notes (E. S. R., 10, p. 646).

Twelfth Annual Report of Maryland Station, 1899 (*Maryland Sta. Rpt. 1899, pp. IX+212*).—In addition to brief notes on the work of the station, a meteorological summary for 1898, and a financial statement for the fiscal year ended June 30, 1899, the report contains reprints of Bulletins 57–62 of the station on the following subjects: Report on the San José scale in Maryland and remedies for its suppression and control (E. S. R., 10, p. 868), the Hessian fly and wheat diseases (E. S. R., 10, pp. 864, 872), sweet potato insects (E. S. R., 11, p. 52), some diseases of the sweet potato (E. S. R., 11, p. 260), the sugar beet in Maryland (E. S. R., 11, p. 441), experiments with wheat, corn, and potatoes (E. S. R., 11, p. 440).

Eleventh Annual Report of Mississippi Station, 1898 (*Mississippi Sta. Rpt. 1898, pp. 13+57*).—Contains the organization list of the station, a brief review of station work by the director, a meteorological report noted elsewhere, and a financial statement for the fiscal year ended June 30, 1898. Reprints of Bulletins 43, 44, 49, and

50 of the station on the following subjects are appended: Natural plant food, claims made for it and its value (E. S. R., 9, p. 1043), winter pasture (E. S. R., 9, p. 1048), analyses of commercial fertilizers (E. S. R., 10, p. 428), winter and summer pasture in Mississippi (E. S. R., 10, p. 547).

Tenth Annual Report of Nevada Station, 1897 (*Nevada Sta. Rpt. 1897, pp. 29*).—The different lines of station work are reviewed by the director and heads of departments, and a financial statement is given for the fiscal year ended June 30, 1897.

Twelfth Annual Report of New York Cornell Station, 1899 (*New York Cornell Sta. Rpt. 1899, pp. XXI+711*).—The report proper contains the organization list of the station and brief reports by the director, treasurer, and heads of departments. Appendix I is made up of reprints of Bulletins 150–170 of the station on the following subjects: Tuberculosis in cattle and its control (E. S. R., 10, p. 596), gravity or dilution separators (E. S. R., 10, p. 591), studies in milk secretion (E. S. R., 10, p. 885), impressions of our fruit-growing industries (E. S. R., 10, p. 959), tables for computing rations for farm animals (E. S. R., 10, p. 992), San José scale (E. S. R., 10, p. 975), third report on potato culture (E. S. R., 10, p. 950), the grape-vine flea-beetle (E. S. R., 10, p. 1073), source of gas and taint-producing bacteria in cheese curd (E. S. R., 10, p. 1093), an effort to help the farmer (E. S. R., 10, p. 1098), hints on rural school grounds (E. S. R., 11, p. 50), annual flowers (E. S. R., 11, p. 49), the period of gestation in cows (E. S. R., 11, p. 81), fungus diseases of the sugar beet (E. S. R., 11, p. 162), peach-leaf curl (E. S. R., 11, p. 161), ropiness in milk and cream (E. S. R., 11, p. 282), sugar-beet investigations for 1898 (E. S. R., 11, p. 237), the construction of the stave silo (E. S. R., 11, p. 294), studies and illustrations of mushrooms, II (E. S. R., 11, p. 322), studies in milk secretion (E. S. R., 11, p. 381), tent caterpillars (E. S. R., 11, p. 368). Appendix II gives a detailed statement of receipts and expenditures of the station for the fiscal year ended June 30, 1899. Appendix III contains reprints of publications on nature study.

Ninth Annual Report of North Dakota Station, 1898 (*North Dakota Sta. Rpt. 1898, pp. 36*).—This contains the board of trustees and staff of the station; a financial statement for the fiscal year ended June 30, 1898; brief reports by the director and heads of the departments of agriculture, horticulture, and dairying; and more extended reports by the chemist, botanist, and veterinarian, noted elsewhere.

Seventh Annual Report of Washington Station, 1897 (*Washington Sta. Rpt. 1897, pp. 8*).—This includes the board of control and station staff, a brief review of station work by the director, and a financial statement for the fiscal year ended June 30, 1897.

Practical value of the work of the experiment station, H. J. WATERS (*Missouri Sta. Circ. of Information 9, pp. 7*).—Results obtained in some of the more important lines of work carried on at the station are briefly mentioned.

List of reports and bulletins published up to December 31, 1898 (*Indiana Sta. Circ. 1, pp. 8*).—Subject list of publications of the school of agriculture from 1885 to 1887 and of the station since 1888.

Crop circular for September, 1899, J. HYDE (*U. S. Dept. Agr., Division of Statistics Crop Circ., Sept., 1899, pp. 4*).

Crop circular for November, 1899, J. HYDE (*U. S. Dept. Agr., Division of Statistics Crop Circ., Nov., 1899, pp. 4*).

The rice industry, J. SHOMAKER (*Irrig. Age, 14 (1900), No. 5, pp. 170, 171*).—A note on the status of this industry in the United States at the present time.

Agriculture in Holland (*Jour. Bd. Agr. [London], 6 (1899), No. 3, pp. 369–373*).—Statistical data on area under cultivation, crop production, wages, etc.

Agricultural education in rural schools—a suggested English scheme (*Farmers' Gaz., 58 (1899), No. 52, pp. 1132, 1133*).

Agricultural education (*Nature, 61 (1900), No. 1579, pp. 332, 333*).—Suggestions for the elementary teaching of agriculture in England.

Report of committee respecting the establishment of an agricultural department and experiment station (*Jour. Jamaica Agr. Soc., 4 (1900), No. 1, pp. 30–45*).

NOTES.

Connecticut State Station.—B. W. Collins, of Meriden, has been elected a member of the board of control for a period of two years in place of S. M. Wells, whose term of office has expired.

Georgia Station.—A. V. Deadwyler, member of the board of directors of the station, has resigned, and John Deadwyler has been appointed his successor. The horticultural department of the station has undertaken tests of the culture of hybrid oranges furnished by this Department, and has begun experiments in tea culture.

Mississippi College.—At a recent meeting of the board of trustees J. C. Hardy, formerly superintendent of the public schools of Jackson, was elected president of the college to succeed J. M. Stone, deceased.

Missouri College and Station.—The station has just forwarded to Texas four carloads of northern pure-bred cattle, both bulls and heifers. These cattle have been at Columbia for the past three months being inoculated against Texas fever, and have recovered in good condition from the inoculation fever. Two additional carloads from northern Missouri have just been received and will be inoculated at once. The college now has in training, under the direction of Dr. Connaway, three or four young men who are doing the actual work of inoculating and nursing the cattle and who will soon have the requisite experience to conduct such work alone.

New Mexico College and Station.—John J. Vernon, formerly assistant horticulturist in the Iowa Agricultural College and Experiment Station, has been appointed agriculturist in this college and station.

Cornell University.—Arrangements have been made for a course in fish culture in connection with the college of forestry. The course will occupy two weeks, beginning May 7, and will be given at Axton in the college forest in the Adirondacks. It will be under the direction of Prof. Barton W. Evermann, of the United States Fish Commission, and will consist of a series of daily lectures, with laboratory work, field excursions, and visits to the State fish hatchery at Clearwater.

Tennessee University and Station.—The horticultural department has planted an experimental orchard of Tennessee seedling apples and standard varieties of apples, peaches, pears, plums, cherries, and quinces, with representative collections of small fruits. The plantation covers 5 acres of high ridge land, and exemplifies both contour and straight-row planting. The chemical department has been making analyses of cultivated soils from the more important type soils throughout the State, and has been conducting cooperative fertilizer experiments along with the chemical work. The department of agriculture has recently issued an illustrated handbook containing articles on agricultural instruction in the University of Tennessee and on the experimental work of the agricultural department, and chapters on dairying, the orchard, soil and its culture, forage, and botanical work. The object in publishing this book is to give the farmers much needed practical information that can not be secured in the station publications, and to bring them in closer touch with the college of agriculture and the experiment station work.

Utah College and Station.—J. M. Tanner, president of the college, has resigned. The following have been appointed members of the board of trustees:

P. W. Maughan, secretary, *vice* Joseph E. Wilson, resigned, and John A. McAlister, of Logan, *vice* M. W. Merrill, resigned.

VIRGINIA STATION.—Capt. C. E. Vawter has resigned as a member of the governing board. At the recent session of the legislature the governing board of the station was made a board of crop pest commissioners for the eradication of insect enemies and fungus diseases of fruit trees.

WISCONSIN UNIVERSITY AND STATION.—A central heating plant is being completed which will furnish steam heat to the dairy building, the horticultural building with its greenhouses, and to the proposed central agricultural building which it is planned to locate near these two structures. Over the boiler room proper is a two-story structure 30 by 50 ft., which will afford increased accommodations for dairy school instruction. On the first floor will be placed steam engines, pumps for instruction purposes, etc., while the second will furnish accommodations for instruction in pipe cutting, belt lacing, soldering, etc. It has been found desirable to give dairy pupils drill in these lines in order to increase their efficiency in the practical operation of creameries and cheese factories. The structure is of white brick with red brick trimmings and cherry-red tile roof. Plans are now being made for an addition to the dairy building which will provide rooms for the manufacture of Swiss and other varieties of foreign cheese and for the curing and care of cheese. Special rooms are being arranged for a continuation of investigations which are in progress to ascertain the proper temperatures, moisture content, etc., for cheese-curing rooms.

SCHOOL OF FORESTRY AT YALE UNIVERSITY.—A donation of $150,000 has been made to Yale University for the establishment of a school of forestry by Mr. and Mrs. J. W. Pinchot and their sons, Gifford and A. R. Pinchot. The donors also authorize the use of a large tract of land in Pennsylvania for a summer school of forestry. Henry S. Graves, assistant in the Division of Foresty of this Department, has been appointed professor of forestry.

SCHOOL OF APPLIED AGRICULTURE AND HORTICULTURE.—According to American Gardening (21 (1900), No. 270, p. 130), a school for scientific instruction and practical training in agriculture and horticulture is to be established near New York City in connection with the New York Botanical Garden. The matter is in the hands of a committee for the promotion of agriculture. A farm of nearly 200 acres, located at Chappaqua, 33 miles from New York City, has been secured by the committee, and the work of organizing the school will begin at once. The plan of the school, as outlined at a recent meeting of the committee at the house of Hon. Abram S. Hewitt, by George T. Powell of Ghent, N. Y., "embraces the study of scientific principles along elementary lines. Students will also be instructed in the practical details of the culture of plants, in the planting and care of orchards, small fruits, market-garden vegetables, greenhouse culture, dairy work, and poultry raising, getting the fullest knowledge of the best and most skillful methods that are necessary in the production of the finest products that command in all markets the highest value."

O

EXPERIMENT STATION RECORD.

VOL. XI. No. 10.

The investigation recently reported upon by the Missouri and Texas stations in combating Texas fever is an instance of a line of veterinary work in the legitimate province of the station veterinarians, which thorough and persistent investigation has brought to most successful issue. It is likewise a good illustration of the fundamental importance of research along lines which are more or less purely scientific, and the ultimate application of the results in practice.

The work of combating Texas fever has been in progress for a number of years. The Bureau of Animal Industry of this Department demonstrated it to be due to a protozoan blood parasite, and showed experimentally the agency of the cattle tick in carrying this organism and thereby infecting cattle with the disease. It was shown that the disease is not communicated by contact with a diseased animal, but only through infestation with infected ticks. Accordingly experiments were at first directed toward getting rid of the tick by dipping cattle in various materials. In this work the Missouri and Texas stations, as well as several other stations in the South, cooperated for a number of years. Southern cattle were dipped and then shipped North to determine whether they could be safely mixed with herds there, and Northern cattle were shipped South and then dipped for the purpose of preventing their infection by Texas fever. A single dipping was found insufficient to destroy all the ticks, and a frequent repetition of the process was found to be severe on the animals and not entirely effective.

Various attempts were made to render Northern cattle immune to the disease in a manner similar to that in which Southern cattle become immune, that is, by infestation with ticks. Such experiments led to the investigations which have had so successful an outcome. Following the discovery by the Bureau of Animal Industry of the immunizing effect of the blood from immune cattle, a method was worked out and given a practical test. The mild attack developed by a single inoculation was found to confer only partial immunity, which could be rendered complete by a subsequent inoculation.

The Bureau experiments reviewed in the present number were made with ten ordinary grade animals. The work reported by the Missouri and Texas stations was with over four hundred animals, mostly thoroughbreds, and under conditions which were a severe test of the efficacy and practical application of the treatment. In general, thoroughbred cattle are more susceptible to the disease than grade cattle, and from a practical point of view the introduction of high-bred stock into the regions infested by Texas fever is very desirable and has often been attempted. Hence, the work not only demonstrates the reliability of the method on a large scale, but carries with it the solution of an exceedingly important practical problem for the South.

In the present state of the method, when due care is exercised, the loss from inoculation fever or from the development of the disease on account of failure in producing immunity is so small that it may almost be neglected. The loss for all the animals inoculated was less than 8 per cent. When proper regard is had to the condition and age of the animals, to the climatic conditions, and to the care of the animals during the period from the inoculation to complete recovery from the inoculation fever, the method is thoroughly reliable. Northern cattle may be taken into infested regions in winter and under proper precautions immunized in the South, or they may be inoculated and rendered immune in the North before shipment.

The economic importance of this discovery is apparent when it is considered that under ordinary conditions from 40 to 70 per cent of Northern cattle shipped into the infested regions die from the attack of Texas fever. This high rate of mortality has greatly hindered the shipment of high-bred Northern cattle to the Southern States for breeding purposes and for the improvement of beef and dairy herds. Repeated attempts have been made to introduce thoroughbred bulls into Southern herds, but so often with disastrous results as to discourage attempts in this direction. This has exercised a very marked effect on the grade of cattle kept in the South, especially the dairy cattle, and has retarded the development of the dairy industry in that section. The removal of this barrier will probably do more toward promoting the dairy interests of the South than any other single factor in the problem.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

The chemical analysis of phosphate rock, O. A. MOOERS (*Univ. Tennessee Record, 1899, No. 11, pp. 252–255*).—This is an account of a critical study of methods for the complete analysis of mineral phosphates, with recommendations for their improvement. The official molybdic method for the determination of phosphoric acid was used.

> "For the estimation of iron and aluminum oxids the filtrate from the yellow precipitate of ammonium phosphomolybdate is diluted to about 800 cc. and the iron and aluminum precipitated by ammonia. The precipitate after boiling is allowed to settle so that the liquid can be decanted through a filter paper. The precipitate is then added, and after being washed once or twice, is dissolved into the precipitating beaker with dilute HCl. This solution of chlorids is now made up to about 250 cc., 5 cc. of strong HCl added, and the iron and aluminum again carefully precipitated. The third precipitate in this manner is washed free of chlorin, dried and burned, and weighed as iron and aluminum oxids"

A rapid method for the determination of clay in soils, F. POQUILLON (*Bul. Soc. Chim. Paris, 3. ser., 23 (1900), No. 4, pp. 115, 116*).—In the method proposed 10 gm. of the soil is rubbed up with the finger in a porcelain crucible, water being added drop by drop until the volume reaches about 25 cc. The contents of the crucible are then washed into a 150 cc. beaker containing from 100 to 120 cc. of dilute ammonium hydroxid solution (1 gm. per liter). The mixture is stirred with a glass rod, allowed to stand 5 minutes, and the supernatant liquor decanted into a liter flask. From 100 to 125 cc. more of the solution of ammonium hydroxid is added to the residue, stirred, allowed to stand 5 minutes, and decanted as before. This operation is repeated until the liquid is clear, from 6 to 8 washings usually being sufficient even for soils richest in clay. The residue is then treated with dilute hydrochloric acid, washed with distilled water, and weighed, giving the amount of total sand. The washings containing the clay are treated with a few drops of hydrochloric acid to decompose the carbonates and coagulate the clay. The solution is allowed to stand until it becomes clear, which requires from 2 to 3 hours. The clay is then collected on a filter, washed with distilled water, dried, and weighed.

Comparative tests of this and other methods for determining clay indicate that it is fully as accurate and much more rapid than the other methods.

A reducing and invertible sugar obtained from cornstalks, C. ISTRATI and G. OETTINGER (*Bul. Roumaine, 8, pp. 325–351; abs. in Chem. Centbl., 1900, I, No. 1, p. 43*).—In 1897 the authors reported the content of reducing and invertible sugar in the stalks of 13 varieties of corn grown in Bucharest. The present article reports the results for 16 varieties grown in 1898. The object was to determine not only the total quantity of sugar, but the period of growth at which the greatest amount of sugar was present, and the variety best suited to serve as a substitute for the sugar beet. Up to the seventieth day of growth of the plant the juice was nearly always levorotatory, but from that time on it was dextrorotatory.

The article contains detailed tabular statements on the composition of the maize juice, which are not reproduced in the abstract.

Determination of fat in milk, R. LÉZÉ (*Ann. Chim. Analyt. et Appl., 4 (1899), pp. 371, 372; abs. in Chem. Centbl., 1900, I, No. 1, p. 69*).—The following method, based on Ramschen's, has been worked out: In a flask of 50 to 60 cc. capacity, graduated to 0.1 cc., place 36 cc. of milk and 10 cc. of a mixture prepared by dissolving 8 gm. of caustic potash in 10 cc. of pure ammonia, adding 55 cc. of ethyl alcohol and 15 cc. of amyl alcohol, and adding sufficient ammonia to make the volume 100 cc. The milk is digested with this mixture for 10 minutes on a boiling-water bath and warm water then added to bring the separated fat layer into the neck of the flask, reading off the fat layer at a temperature of 40° C. The volume of fat divided by 4 gives the grams of fat in 1 liter of milk.

The results with this method are said to agree well with those obtained by extraction.

Formalin in milk, A. LEYS (*Ann. Chim. Analyt. et Appl., 4 (1899), pp. 338–342; abs. in Analyst, 25 (1900), Feb., p. 37*).—Jorissen's test is the one principally relied upon in the municipal laboratory in Paris. In this 25 cc. of milk is shaken with 10 cc. of a solution of phloroglucin (1 gm. per liter), and subsequently with 5 to 10 cc. of potassium hydroxid. To eliminate the chances of error a preliminary test is made by shaking 10 cc. of the milk with 20 cc. of Adams's ammoniacal mixture of alcohol and ether. If the lower layer is completely opaque after a few seconds, the milk is regarded as having been boiled; a greenish tint with slight flocculence indicates annatto; a red coloration points to the presence of turmeric; while chrysoin gives the upper layer a golden yellow color, and the milk itself gives a reddish-brown tint on treatment with potassium hydroxid. The detection of formalin in the absence of these substances is confirmed by distilling the milk and testing the distillate with Gayon's reagent (1,000 cc. 0.1 per cent aqueous solution of fuchsin, 10 cc. sodium bisulphite solution (30° Bé.), and 10 cc. concentrated hydrochloric acid). The milk is also tested by Denigès's method (E. S. R., 8, p. 459).

Contribution on the albuminoid bodies of cows' milk, II, K. STORCH (*Monatsh. Chem., 20 (1899), pp. 837–846; abs. in Chem. Centbl.,* *1900, I, No. 2, p. 142*).—This continuation of the author's previous investigations (E. S. R., 9, p. 222) is confined to studies of the two phosphore-containing albuminoid bodies, *a* and *b*, previously obtained by saturating cows' milk with sodium sulphate, magnesium sulphate, or sodium chlorid, as a result of the cleavage of the caseinogen. The body *a* is believed to be a nucleoalbumin and *b* a nucleohiston. The preparation of the bodies in pure state is described, together with a long list of reactions and their elementary composition.

Chemical division, H. J. WHEELER (*Rhode Island Sta. Rpt. 1898, pp. 111-121*).—A brief synopsis is given of the work of the year, including fertilizer inspection, study of methods of analysis, field, pot, and greenhouse experiments, special chemical investigations, miscellaneous analyses (see p. 917), etc.

On a possible error in the determination of nitrogen in nitrates due to impurities in reduced iron, B. L. HARTWELL and H. J. WHEELER (*Rhode Island Sta. Rpt. 1898, pp. 204, 205*).—See E. S. R., 11, p. 311.

A general method for the determination of elements in organic compounds, BERTHELOT (*Compt. Rend. Acad. Sci. Paris, 129 (1899), pp. 1002-1005; abs. in Chem. Centbl., 1900, I, No. 5, p. 316*).—The author gives the means of determining the elements of a compound by combustion in the bomb calorimeter. The combustion in the bomb leads to practically the same results as ordinary combustion and incineration.

A new method for determining water in sirups and similar products, O. MOLENDA (*Oesterr. Ztschr. Zuckerind. u. Landw., 28 (1899), pp. 621-625; abs. in Chem. Centbl., 1900, I, No. 1, p. 71*).—The method depends upon the familiar decomposition process of calcium carbid with water, the acetylen generated being taken as an indication of the water content.

Detection of sawdust in flour, G. A. LEROY (*Ann. Chim. Analyt. et Appl., 4 (1899), pp. 212-221; abs. in Analyst, 25 (1900), Feb., p. 39*).—The author uses an acid solution of phloroglucin.

On the abnormally high polarization of some cane juices, H. C. PRINSEN-GEERLIGS (*Internat. Sugar Jour., 2 (1900), No. 15, pp. 145-153*).

The preparation in pure state and the separation of sugars, O. RUFF and G. OLLENDORFF (*Ber. Deut. Chem. Gesell., 32 (1899), pp. 3234-3237; abs. in Chem. Centbl., 1900, I, No. 1, p. 19*).—The authors recommend the substitution product benzyl phenylhydrazin as superior to phenylhydrazin.

A modification of Duclaux's method for determining solids and fat in milk and butter, U. MORINI (*Staz. Sper. Agr. Ital., 32 (1899), pp. 517-530; abs. in Chem. Centbl., 1900, I, No. 1, p. 69*).—Duclaux's method is said to be suited to the examination of butter which contains an unusually large amount of water and protein substances, but the author uses 20 gm. of butter instead of 2 to 3 gm. as recommended by Duclaux, and recommends for the extraction of the fat the apparatus described by O. Förster.[1]

In conclusion the author describes the method in detail and reports analyses showing the utility of the modified Duclaux method.

Annual report of the chemical laboratory of the city of Altona, 1898-99, A. REINSCH (*Abs. in Chem. Centbl., 1900, I, No. 5, p. 308*).—Of 187 samples of butter 24 contained over 16 per cent of water, and 16 had more than 20 per cent. By means of the sesame oil test 2 samples of butter with saponification numbers of 227.3 and 226.8 and Reichert-Meissl numbers of 24.98 and 25.48, respectively, were shown to be adulterated with oleomargarine; without this test the adulteration would not have been detected. The refractometer with Wollny's special thermometer was found to be of very little use as a preliminary test of butter.

Data are given for sausage, honey, wines, and other products examined.

---

[1] Ztschr. Analyt. Chem., 27 (1888), p. 30.

Retention of moisture by asbestos, G. AUCHY (*Jour. Amer. Chem. Soc., 22 (1900), No. 1, pp. 46, 47*).—The author calls attention to the fact that asbestos may retain moisture with such tenacity as not to be driven off by drying at 100° C., and points out the bearing of this in making determinations with the Gooch crucible. He recommends "either to get the preliminary weight of the Gooch crucible by drying the same length of time and at the same temperature as is intended with the precipitate, or, much more conveniently, to find once for all the weight of the moisture retained by the dried Gooch crucible and make the necessary correction when getting weights of precipitates."

On some analyses of modern "dry" champagne, O. ROSENHEIM and P. SCHIDROWITZ (*Analyst, 25 (1900), Jan., pp. 6-9*).—A tabulation of 13 analyses of this class of wines shows the unreliability of judging wines on purely analytical data.—G. W. SHAW.

The pectin of the quince, JAVILLIER (*Jour. Pharm. et Chim., 6. ser., 9 (1899), pp. 163-166, 513-515; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 12, pp. 932, 933*).—A chemical study of the pectin obtained from quince pulp.

The pectin of gooseberries, E. BOURQUELOT and H. HÉRISSEY (*Jour. Pharm et Chim., 6. ser., 9 (1899), pp. 281-286; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 12, p. 933*).—A chemical study of the pectin of the gooseberry.

BOTANY.

The probable cause of the poisonous effects of the darnel, P. GUÉRIN (*Bot. Gaz., 28 (1899), No. 2, pp. 136, 137*).—In the author's investigations upon seed integuments and the pericarp of grasses, he noted the practically constant presence in the seeds of the darnel of a fungus to which it seems reasonable to assign its poisonous effects. This fungus, which is always present in the form of a mycelium, appears at an early stage in the interior of the ovary. In the first stages of its development it is said to invade the entire nucellus, and at the time that the external integument of the ovule disappears the nucellus itself is almost entirely resorbed. These observations have been confirmed in other species of Lolium, although the fungus occurs rarely upon *L. perenne.*

The exact nature of the fungus is not yet definitely settled, but the author states that it can not be identified with *Endoconidium temulentum.* The latter fungus attacks the seeds of rye, which it seriously deforms, while darnel shows no such deformation.

The effect of algæ on greenhouse plants, A. MAURIZIO (*Flora, 86 (1899), No. 2, pp. 113-142, pl. 1*).—Attention is directed to a number of investigations on the effect of algæ on plants, especially the parasitic algæ of the Tropics, and deductions as to those growing on greenhouse plants are drawn.

The species most under investigation, which were on greenhouse plants exclusively, were *Pleurococcus vulgaris*, *Cystococcus humicola*, *Oscillaria tenuis*, *O. subtilissima*, *Stichococcus bacillaris*, *Chroococcus helveticus*, *Protococcus botryoides*, and *Merismopœdia elegans*. The plants attacked are divided into 3 classes: (1) those whose leaves have thin or poorly developed epidermis, among these the ferns; (2) plants with one or more layers of epidermal cells, in which cases injury is by covering the leaves with matted algæ; and (3) those with a very thick epidermis with little cuticularization.

The method by which each group of plants is affected is described at considerable length. One of the principal ways is by covering the plants to such an extent that the functions of the leaves are interfered with and the general vitality of the plant impaired.

A bibliography of the subject completes the paper.

The effect of static electricity on the roots of plants, A. LETELLIER (*Bul. Soc. Bot. France, 46 (1899), No. 1–2, pp. 11–23*).—By means of an especially arranged clinostat the author was enabled to investigate the effect of static electricity upon the roots of beans, the influence of gravity, moisture, temperature, and atmospheric electricity being eliminated. It was found under the conditions of the experiment that positive static electricity exerts a strong directive influence upon the primary and secondary roots of the bean. Negative static electricity also exerts a directive force, but less powerful. Both results may be platted in curves having opposite direction to that exerted by electrified disks.

Report of the agricultural-climatological station at Juvisy, C. FLAMMARION (*Bul. [Min. Agr. France], 18 (1899), No. 3, pp. 438–450, figs. 3*).—This report covers investigations on the effect of solar radiation on the growth of plants, the persistence of oak leaves under the influence of blue rays, the action of the different portions of the spectrum upon the coloration of plant tissues, the action of different portions of the spectrum upon the growth of silkworms, and the rate of transpiration in some plants.

The experiments on solar radiation as affecting the growth of plants are in continuation of those previously described (E. S. R., 10, pp. 103, 613), and are being conducted with special reference to uniformity in temperature and intensity of light. Plants were grown in different portions of the spectrum, in double bell jars, the space being filled with monochromatic solutions, and in houses furnished with different colored glass. As previously, the best growth was made in the red light, and intensity of light was found to play an unimportant rôle. Slight differences were observed, but in general both woody and herbaceous plants acted alike in their response to different light conditions.

In the above experiments with small oak trees grown in large pots, it was observed that the trees under the blue light retained their leaves far longer than the others. This is explained by the fact that blue light retarded the ordinary processes of growth, the chlorophyll being very slowly acted upon, the circulation rendered very sluggish, and the trees kept in a very low state of existence.

The color of plants was influenced to a marked degree by the different lights in which they were grown. Plants with bright foliage and flowers were grown for a time under different colored lights with a decided effect upon the clearness of their tints. This was true of Alteranthera, begonias, geraniums, Cobæa, verbenas, lobelias, and Tradescantia.

The action of different colored light upon silkworms was investigated by placing 15 worms of the same size under different colored lights and weighing them after about 5 weeks. Those grown under the orange light were the heaviest, followed by those grown under red, blue, black, and clear glass, respectively. The experiments are to be repeated.

The relative amount of water transpired by a lily flower and leaf was investigated. The weight of the flower was about 6 times that of the leaf, but the latter transpired in 24 hours 11 times as much water as the flower. The author thinks that the white color of the flower had considerable to do with the low transpiration. The transpiration of maize plants of 0.15 meter height when grown under monochromatic colors was studied. Those grown under the visible spectrum transpired most per gram weight of leaf, followed by those grown under total radiation, orange, red, pale blue, deep blue, green, and darkness under a lampblack screen.

The acquisition of atmospheric nitrogen by soil inoculation, W. M. MUNSON (*Maine Sta. Rpt. 1898, pp. 208–212*).—Experiments were conducted with red clover, peas, vetches, beans, and soja beans, with different kinds of Nitragin cultures. The experiments were conducted in a sandy subsoil placed in a tight box and sterilized by passing a steam coil for one hour through the soil.

The results for each plant are given in detail, and the general conclusion is drawn that the culture of the specific germ of any given type gave no better results than a culture of a nearly related type. In most cases plants from untreated pots were as vigorous as those from inoculated soil. The experiments thus far conducted do not warrant the recommendation of germ cultures for leguminous crops.

A trial of Nitragin, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1898, pp. 186–191, fig. 1*).—The authors report experiments conducted with Nitragin, in which 4 plats containing 100 sq. ft. each, on which leguminous plants had not previously been grown for 20 years or more, were fertilized with 300 lbs. of muriate of potash and 800 lbs. of acid phosphate, and plats 3 and 4 received 300 lbs. per acre of air-slaked lime. The bacteria culture, after being warmed according to direction, was divided into 2 equal parts and thoroughly mixed with water at suitable temperature. One portion was sprinkled over plat 1, the other over plat 3. Four rows of American Wonder peas were planted in each plat. On July 29 the peas had made a full growth and were cut close to the ground, and their weights taken green. In each case the plats receiving no culture solution gave slightly the heavier yield. Examination of the roots of the plants showed that where inoculation had taken place the roots were covered with small tubercles, although on one of the check plats a number of nodules were distinguished.

Immediately after the removal of the first crop, a second crop of peas was planted with similar results. It was observed that even on the plats which received no Nitragin there were uniformly large numbers of tubercles upon the roots of the plants.

The authors state that the absence of any particular benefit in the case of the first crop was probably due to the presence of sufficient combined nitrogen in an assimilable form to supply the needs of the plants. In the second case the lack of apparent benefit was probably due to the above cause and to the fact that the organisms naturally present had multiplied to such an extent as to insure an abundant assimilation of atmospheric nitrogen without the intervention of those supplied by the Nitragin.

The flora of North Carolina, C. W. HYAMS (*North Carolina Sta. Bul. 164, pp. 290–365*).—A list is given of the flowering plants and higher cryptogams known to occur within the borders of the State. In all, 2,685 species are mentioned and their distribution in the different parts of the State indicated.

Notes on the plants of the year, F. L. HARVEY (*Maine Sta. Rpt. 1898, pp. 131–135*).—Notes are given on the plants received during the year for identification, from which it is thought that the farmers of the State are awakening to the importance of weeds, and the necessity of carefully watching their fields to prevent the introduction and spread of weeds. A large number of seeds are reported to have been examined during the past season, over 60 kinds of foreign weed seed having been detected.

Preliminary catalogue of plants poisonous to stock, V. K. CHESNUT (*U. S. Dept. Agr., Bureau of Animal Industry, Rpt. 1898, pp. 387–420, figs. 32*).—Most of the species here given are described in Bulletin 20 of the Division of Botany of this Department (E. S. R., 10, p. 516). The present catalogue includes a larger number of introduced and native plants which have been reputed as more or less poisonous to stock. Lists are given of plants which are claimed to be poisonous to stock, those probably poisonous, and those suspected of being injurious.

British parasitic flowering plants, J. SAUNDERS (*Trans. Herfordshire Nat. Hist. Soc., 10 (1899), No. 2, pp. 44–48*).—A list is given of the parasitic phanerogams occurring in Great Britain, together with their distribution and habitat.

Catalogue of herbarium specimens for exchange, C. W. HYAMS (*North Carolina Sta. Spec. Bul. 51, pp. 48*).—A list is given of duplicate specimens which are offered in exchange to other institutions or persons desiring them.

Plant structures, J. M. COULTER (*New York: D. Appleton, 1900, pp. VII+348, figs. 289*).—This book, which is termed a second book in botany, is supplemental to Plant Relations by the same author (E. S. R., 11, p. 709), and each is meant to represent a half year's work in secondary schools. While in Plant Relations ecology dominates the work, in this volume plant morphology is the keynote, and for those teachers of botany who believe morphology should come first in the course of study, the order of the two may be reversed. After tracing the evolution of the plant kingdom from the lowest to the highest, chapters are given on physiology, ecology, and taxonomy, in which the main facts are brought together. A brief glossary is appended in which the necessary terms are defined, but untechnical terms are used so far as possible.

The numerous illustrations of both Plant Relations and Plant Structures are to be studied as diligently as the text. In the study of botany the author states that "the book is merely intended to serve as a compact supplement to the three more important factors—the teacher, the laboratory, and fieldwork."

Pollination and fertilization of flowers, W. M. MUNSON (*Maine Sta. Rpt. 1898, pp. 218–229, pls. 5*).—The author undertook the study of some of the problems connected with the pollination of flowers, and the results given in a previous report of the station (E. S. R., 4, p. 544), since which time press of other duties has made it impossible to continue the work. Opportunity offering for the continuation of this line of experimentation, the present report summarizes some of the more prominent features previously considered and outlines the work to be undertaken. The points for special consideration are the growth of the pollen tube, a revision of the list of species supposed to show immediate effects of pollen, the stimulating action of pollen, and the possibility of superfœtation.

The laws regulating the sexes of flowers, T. MEEHAN (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 536–548, figs. 4*).—The author maintains that in plants the question of male or female is wholly a question of nutrition.

Leaves and their uses, J. HOOPES (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 677–694, figs. 4*).—The structure and function of leaves are described in a somewhat popular manner.

The plant food in the leaves of the sycamore and its transportation with the growth and the dying of the leaves, G. M. TUCKER and B. TOLLENS (*Ber. Deut. Chem. Gesell., 32 (1899), p. 2575; abs. in Chem. Ztg., 23 (1899), No. 90, Repert., p. 324*).

Photosynthesis in the evergreen leaves during the winter months, K. MIYABE (*Bot. Centbl., 80 (1899), No. 5, p. 172*).—The starch content of leaves fell from November to the end of January. The starch began to accumulate again in February.

Transpiration of evergreen trees during winter, S. KUSANO (*Bot. Centbl., 80 (1899), No. 5, p. 171*).

On the transmission of growth characteristics through selected seed, CLAUSEN (*Jour. Landw., 47 (1899), No. 4, pp. 391–430*).

On the growth of bamboo shoots, K. SHIBATA (*Bot. Centbl., 80 (1899), No. 5, pp. 169, 170*).

The grafting of monocotyledons (*Gard. Chron., 3. ser., 26 (1899), No. 674, p. 398*).—Success is claimed in grafting several species of the above.

Concerning the grafting of monocotyledons, L. DANIEL (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 17, pp. 654–656*).—A note is given of the successful grafting and forming of a union in a number of experiments with monocotyledonous plants.

Concerning the existence of Penicillium glaucum in solutions of various organic salts, A. YASUDA (*Bot. Mag. [Tokyo], 13 (1899), No. 152, pp. 309–316*).

Additions to the knowledge of endotropic mycorrhiza, S. BERNÁTSKY (*Termeszet. Fuzetek, 1899, p. 88, pls. 2; abs. in Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 16–17, p. 603*)

The so-called invisible injury by smoke and fumes, P. SORAUER and E. RAMANN (*Bot. Centbl., 80 (1899), Nos. 2–3, pp. 50–56; 4, pp. 106–116; 5, pp. 156–168; 6, pp. 205–216; 7, pp. 251–262*).

The behavior of algæ and fungi to certain chemicals, N. ONO (*Bot. Centbl., 80 (1899), No. 5, pp. 170, 171*).

On the toxic effect of deleterious agents on the germination and development of certain filamentous fungi, J. F. CLARK (*Bot. Gaz., 28 (1899), No. 5, pp. 289–327, dgms. 8*).—A report is given on the effect of a large number of deleterious agents, as shown on the germination and growth of a number of fungi, among them, *Aspergillus flavus*, *Sterigmatocystis nigra*, *Œdocephalum albidum*, and *Penicillium glaucum*.

Plant swellings, P. SORAUER (*Ber. Deut. Bot. Gesell., 17 (1899), No. 10, pp 456–460, fig. 1*).—Accounts are given of a number of plants showing excrescent growths which are attributed to a disturbance of the equilibrium between the functions of the plant.

On the histological modification produced by the action of Phytoptus, M. MOLLIARD (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 21, pp. 841–844*).—Notes are given on the histological changes which are brought about in stems by the attacks of various species of Phytoptus, as shown from the structure of the galls.

Experimental investigations on the dwarfing of plants, P. GAUCHERY (*Ann. Sci. Nat. Bot., 8. ser., 9 (1899), Nos. 1, pp. 61–64; 2–4, pp. 65–156, pls. 4, figs. 32*).—A large number of experiments on dwarfing plants are described and the effects, as shown in the morphology and anatomy of the different plant members, are stated.

Is there a solution to the nitrogen problem? H. W. CONN (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 717–734, figs. 4*).—After reviewing tho nitrogen requirements of plants, the author describes nitrifying and denitrifying bacteria and their methods of action. The fixation of nitrogen by the bacteria in the tubercles occurring on the roots of leguminous plants is described at some length, and the value of commercial products of soil bacteria commented upon.

A new register for studies in plant physiology, J. BARANETSKY (*Ber. Deut. Bot. Gesell., 17 (1899), No. 6, pp. 190–194, pl. 1*).—Describes an electric apparatus for registering growth and other phenomena of plants.

METEOROLOGY.

Meteorological report, N. HELME (*Rhode Island Sta. Rpt. 1898, pp. 212–229*).—This includes general notes on the weather during 1898, and a tabulated record of observations at Kingston on temperature, precipitation, cloudiness, and prevailing winds during each month of 1898, with a summary for the years 1890 to 1898 inclusive. The summary for 1898 is as follows:

Temperature (degrees F.).—Maximum, 95, July 3; minimum, —4, December 14; mean, 48.8; highest monthly mean, 71, August; lowest monthly mean, 27.9, January; highest daily mean, 80, September 1; lowest daily mean, 6, February 2. *Precipitation* (inches).—Total (rain and melted snow), 72.21; greatest monthly, 12.05, October; least monthly, 0.77, June; greatest in 24 consecutive hours, 5.5, July 13; snow fall—total, 59.75; greatest monthly, 20, November; least monthly, 1.75, December. *Weather.*—Number of clear days, 110; number of fair days, 114; number of cloudy days, 141; number of days on which there was precipitation of 0.01 in. or more, 131. *Prevailing wind,* west and southwest.

Meteorological observations at the experiment station of Kagok, Java, during ten years, 1889-1898, H. C. PRINSEN-GEERLIGS (*Meded. Proefstat. Suikerriet, West Java, No. 40, pp. 43, chart 1*).—This includes monthly and yearly summaries of observations on temperature, humidity of the air, soil temperatures (at depths of from 30 to 120 cm.), atmospheric pressure, cloudiness, wind movement, rainfall, number of cloudy days, evaporation, and storms.

During 1898 the hours of sunshine were also recorded. The rainfall for the 10 years, calculated to 5-day periods, is shown in a table and in a diagram.

The temperature is shown to be extremely uniform, the mean for 10 years being 26.4° C. The mean relative humidity of the air for the same period was 80; atmospheric pressure (at 0° C.), 755.4 mm.; rainfall, 2086.5 mm.; rainy days, 170; evaporation in 24 hours, 1.1 mm.; sunshine, 55 per cent of the possible.

Weather influences on farm and garden crops, E. MAWLEY (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 4, pp. 720–745, figs. 6*).—This is the annual address of the president of the Royal

Meteorological Society.[1] It gives a brief sketch of the climate of the British Isles; discusses the relation of temperature, frosts, rain, droughts, snow, sunshine, and wind to the growth of crops; and suggests various means of meeting adverse weather conditions. Meteorological data covering long periods are given in tables, charts, and diagrams.

The climate of Great Britain is shown to be characterized by frequent changes and the absence of extremes. From a table prepared by Sir Henry Gilbert,[2] giving the excess of daily temperature above 42° F. (5.55° C.) during the growing periods for 18 years, it is shown that the average amount of accumulated heat required to grow and ripen wheat at Rothamsted was 1896° F. The difference between the greatest and the least amount required was about 300° F. "This appears to be a very large range indeed, and shows that such calculations can only be regarded as rough approximations, at all events as far as the leading cereal crop in this country is concerned."

Meteorological observations (*Maine Sta. Rpt. 1898, pp. 230, 231*).—This is a monthly summary of observations at Orono during 1898 on atmospheric pressure, temperature, precipitation, cloudiness, and wind movement. The mean temperature for the year was 43.8 F. (mean for 30 years 42.3°), mean pressure 29.84 in., precipitation 49.82 in. (mean for 30 years 45.37), and number of cloudy days 138.

Meteorological chart of the Great Lakes—summary for the season of 1899, A. J. HENRY and N. B. CONGER (*U. S. Dept. Agr., Weather Bureau, Meteorological Chart of Great Lakes, 2 (1899), No. 9, pp. 28, charts 12*).—This is a summary of observations in the lake region during 1899 on storms, atmospheric precipitation, fog, ice, evaporation, and wrecks and casualties.

Snowfall and water supply of the Rocky Mountains, H. A. CRAFTS (*Sci. Amer., 82 (1900), No. 9, p. 133, fig. 1*).—A brief discussion relating especially to the head waters of the Big Laramie and Cache la Poudre rivers.

SOILS—FERTILIZERS.

The soils of the Pecos Valley, New Mexico, T. H. MEANS and F. D. GARDNER (*U. S. Dept. Agr., Division of Soils Circ. 3, pp. 7*).—This is a preliminary report on observations and investigations during 1899 in the irrigated districts around Carlsbad, Roswell, and Hagerman, in New Mexico, and Barstow, Tex., the object of which was "to map the soils of the irrigated districts of this region with particular reference to the extent of and damage from alkali and seepage waters, and to investigate methods for the prevention of further damage, and for the reclamation of lands already abandoned from these causes." The climate, drainage area, irrigation systems, and soils of the region are briefly discussed. The rise of the water table due to excessive or careless irrigation, and the accumulation of alkali due to the same causes and to rapid evaporation in the reservoirs and in the soil, constitute serious menaces to the agriculture of the region. Drainage is generally recommended, except for the soils underlaid by gypsum, on which it is believed it would prove too expensive, on account of their great capillary powers and rapid evaporation.

---

[1] Quart. Jour. Roy. Met. Soc. [London], 24 (1899).

[2] See also Arch. Sci. Phys. et Nat., 3. ser., 16 (1886), p. 421 (Rothamsted Memoirs, vol. 6).

The locust as a fertilizer, J. HÜNCKEL D'HERCULAIS (*La langosta como abono. Min. Agr. Argentine Republic, 1899, pp. 12*).—Chemical analyses and field experiments are reported. According to the analyses of Müntz and Girard, the locust has the following composition:

Fertilizer constituents in locusts.

	Nitrogen.	Phosphoric acid.	Potash.
	Per cent.	*Per cent.*	*Per cent.*
Fresh locusts	3.15	0.60	0.28
Dry locusts	11.50	2.18	1.02
Dry and fat-free locusts	14.00	2.50	1.60

In the pomace obtained by treating the locusts with superheated steam and alkali to remove the fat, there were found 11 to 12 per cent of nitrogen, 1 to 2 per cent of phosphoric acid, and about 0.5 per cent of potash. Analyses with reference to the food constituents of the locust are also reported. In plat experiments the locusts were used at rates of 400 to 600 kg. per hectare, alone or mixed with other materials, in comparison with other fertilizers. When used alone they were not very effective, apparently on account of the large amount of fat which they contain. The fertilizing effect was very greatly increased by the addition of superphosphate. The author suggests that treatment to remove the fat would not only increase the effectiveness of the material, but also prevent the offensive decomposition which takes place when the untreated material is applied to the soil.

Box experiments with phosphoric acid from different sources, L. H. MERRILL (*Maine Sta. Rpt. 1898, pp. 64–74, pls. 7, dgms. 2*).—This is a summary of all the results thus far obtained in these experiments, including those previously published (E. S. R., 9, p. 436).

The plants which have been experimented with include 7 orders: Peas, horse beans, clover, and alfalfa (Leguminosæ); turnips, ruta-bagas, cauliflower, and kohl-rabi (Cruciferæ); barley, corn, oats, and timothy (Gramineæ); tomatoes and potatoes (Solanaceæ); carrots and parsnips (Umbelliferæ); buckwheat (Polygonaceæ); sunflowers (Compositæ).

The results are briefly summarized as follows:

"(1) Plants differ in their ability to feed upon crude phosphates.

"(2) Turnips, ruta-bagas, cauliflowers, and kohl-rabi gave nearly as good returns with the Florida rock as with the acid rock.

"(3) In every other case the good effect of the acid rock was very marked.

"(4) In most cases the crude Florida rock yielded better returns than the Redonda.

"(5) Barley, corn, and oats seem to require an acid phosphate.

"(6) When early maturity is desired, the acid rock can profitably be used.

"(7) The largely increased production obtained by the use of the acid rock will often determine the success of the crop.

"(8) The solubility of a phosphate in ammonium citrate is not always the correct measure of its actual value to the plant."

Upon the possibility of drawing erroneous conclusions from plant soil tests designed as guides to the economical manurial treatment of soils, and to serve as a basis for the development of reliable chemical methods for ascertaining their requirements, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1898, pp. 122-132, pls. 5*).—This article briefly reviews the history of experiments at the station on this subject which were begun in 1890 (E. S. R., 10, p. 937), bringing the account up to the close of the year 1898.[1] The method followed in 1898 was practically the same as that pursued in previous years. The conclusions reached from the 9 years' experiments are briefly summarized as follows:

"(1) Before liming, phosphoric acid was more needed than nitrogen or potash.

"(2) After liming, the soil stood less in need of phosphoric acid than of potash or nitrogen.

"(3) Large quantities of phosphoric acid which had heretofore been largely unassimilable were made of use to plants by treating the soil with lime.

"(4) The above points should be taken into account, and lime applied to all the plats of a soil test when experimenting with such soils as are acid or in other respects stand in need of liming.

"(5) In attempting to secure chemical methods for showing the manurial requirements of soils, as based upon soil tests with plants, erroneous conclusions may be drawn as to their relative reliability if the other ingredients of which the soil stands in need are not applied to all of the plats before the tests as to the relative deficiency of potash, phosphoric acid, and nitrogen are begun.

"(6) One plant may not necessarily answer the question satisfactorily as to the manurial requirements of all other plants upon the same soil.

"(7) At least before liming, maize answers the question satisfactorily as to deficiencies of phosphoric acid, not only for the other cereals, but also for millet, beets, and many other crops.

"(8) Soil tests, designed to show what manurial substances will be yielded to plants in the least quantity for a series of years, must be continued for several seasons before final conclusions can safely be drawn."

On the effectiveness of nitrate of potash as compared with like amounts of nitrogen and potash in form of muriate of potash and nitrate of soda, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1898, pp. 133-136*).—These experiments were begun in 1895 (E. S. R., 10, p. 938). The experiments were conducted on the same plan in 1898 as in previous years, the crops grown being grass and mangel-wurzels.

"In every case, both with grass and mangel-wurzels, a greater total yield was obtained where nitrate of soda and muriate of potash were employed than in connection with like amounts of potash and nitrogen in form of nitrate of potash.

"In view of the perfect harmony, in this particular, of all the results, it seems probable that some special value must be ascribed to the soda or chlorin, or, possibly, to both. . . . .

---

[1] An abstract of this paper will be found in U. S. Dept. Agr., Office of Experiment Stations Bul. 65, p. 113 (E. S. R., 10, p. 711).

"A continuation of this experiment for a few years more ought to furnish some positive information as to the worthlessness or possible value of the soda and chlorin of nitrate of soda and muriate of potash, which have heretofore been quite generally looked upon as ingredients of little or no agricultural value."

The fifth year's observations on the substitution of soda for and its value in connection with potash, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1898, pp. 137–143, pls. 7*).—This is an account of a continuation during 1898 of experiments begun in 1894 (E. S. R., 10, p. 938). The plan followed in 1898 was the same as in previous experiments. The crops grown were oats and millet.

"The results for the year 1898 show the marked inferiority of soda when used without potash as compared with potash when used without soda, corroborating fully in this respect the experience of previous years.

"When the potash supply was reduced to a quarter ration the soda proved quite effective. Where the potash supply was equivalent to half and three-quarter rations the soda seemed to be far less effective than in 1897."

The sixth year's observations upon the growth of plants upon an acid upland soil, limed and unlimed, H. J. WHEELER and J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1898, pp. 144–170, pls. 4*).—The same methods were pursued in these experiments in 1898 as in previous years (E. S. R., 10, p. 939), except that in 1898, as in 1897, the quantities of nitrogen applied were one-third as great as in former years (85.5 lbs. of sulphate of ammonia and 116.25 lbs. of nitrate of soda per acre), and muriate of potash and dissolved boneblack were applied at rates of 300 and 800 lbs., respectively. No lime has been applied since 1894. A number of new crops were introduced into the experiments in 1898, bringing the total number of varieties experimented with up to about 120. The new crops employed in 1898 included white mustard, parsley, Swiss chard, chicory, leeks, garlic, endive, dwarf broom corn, aster, sweet peas, and poppy. Tables show the yields of the various crops grown and give a record of measurements in the spring and autumn of 1898 of the diameters of various fruit and forest trees experimented with.

"Strawberries appear to have been helped by lime on very acid soil. . . .

"Asparagus has been wonderfully helped by lime. The superiority of nitrate of soda, as compared with sulphate of ammonia, for this plant was also most striking, affording a strong contrast in this particular with blackberries.

"Rhubarb was apparently helped by lime, though in a small degree as compared with asparagus. Nitrate of soda also proved slightly more effective than sulphate of ammonia as a source of nitrogen.

"White mustard showed moderate benefit from liming, and indicated the superiority of nitrate of soda as a form of nitrogen.

"Parsley showed little, if any, advantage from the use of lime in connection with nitrate of soda, though on the unlimed sulphate of ammonia plat the results were extremely poor as compared with those where lime was applied. Comparing the two limed plats, but little difference in the two forms of nitrogen was noticeable.

"Swiss chard, like beets, to which it is closely related, was wonderfully helped by lime, and gave far better results with nitrate of soda than with sulphate of ammonia.

"Chicory was not helped, but, on the contrary, apparently injured by lime upon the nitrate of soda plats. Where sulphate of ammonia has been used continuously lime was, however, useful. Sulphate of ammonia gave better results than nitrate of soda on the limed plats.

"Leeks were helped by lime in a most striking degree, even upon the nitrate of soda plats. For this crop the superiority of nitrate of soda as compared with sulphate of ammonia, even upon the limed plats, was also marked.

"Endive plants were materially helped by lime, though in a less degree than asparagus or Swiss chard. These plants showed marked ability to withstand the conditions upon the unlimed sulphate of ammonia plat, where leeks and Swiss chard failed utterly. Nitrate of soda gave better results than sulphate of ammonia upon the limed plats, though the difference was less striking than in the case of many other plants.

"Carrots have indicated, usually, varying benefit from liming upon quite acid soil, but upon a neutral or alkaline one heavy applications might exert injury. . . .

"Mangel-wurzels fully corroborated the experience of previous years, showing striking benefit from the use of lime and great superiority of nitrate of soda over sulphate of ammonia when nitrogen in these forms is employed in like amounts and under identical conditions.

"Watermelons give indication that the great injury otherwise resulting from liming can probably be avoided if the melons are introduced into the rotation three or more years after the lime is applied. This season nitrate of soda proved, when used without lime, but slightly better than sulphate of ammonia, though on the limed plats the nitrate form of nitrogen was much superior.

"Muskmelons have fully agreed with the tests in former years, indicating great benefit from liming and the superiority of nitrogen in the form of nitrate of soda.

"Dwarf broom corn was helped moderately by liming, and on the limed plats the results were identical in the case of both forms of nitrogen.

"Comet aster ('The Bride'), though it was helped by lime, even in connection with nitrate of soda, showed, nevertheless, wonderful ability to withstand the acid condition existing on the unlimed sulphate of ammonia plat where so many other kinds of plants entirely failed. But little difference was noticed between the action of the two forms of nitrogen.

"Sweet peas showed marked advantage from the employment of lime, as shown by the increased weight of vines, and especially by the great increase of blossoms. Many more blossoms and heavier vines were produced by nitrate of soda than by sulphate of ammonia upon the limed plats.

"Poppies seemed to be wonderfully helped by lime, as indicated by the number of blossoms and by the total weight of the plants. Nitrate of soda proved far superior to sulphate of ammonia as a source of nitrogen for this plant. . . .

"The indications thus far afforded go to show that lime has proved especially beneficial to the American linden, elm, and to quince bushes. It appears probable that certain trees, possibly including the white birch and Norway spruce, may be injured by liming, even on very acid soil.

"This season's results with Snyder blackberries are especially interesting, for the reason that in connection with the nitrate of soda plats lime seems to have caused injury, and, furthermore, on account of the superior action of sulphate of ammonia compared with nitrate of soda as a source of nitrogen."

Water conservation in soils, S. M. WOODBRIDGE (*Forester, 5 (1899), No. 8, pp. 181, 182*).—The author gives a popular account of water conservation and points out the necessity of forest cover on mountain sides for the maintenance of stream flow.

Analyses of soils of São Paulo, Brazil, G. D'UTRA (*Bol. Inst. Agr. São Paulo, 10 (1899), No. 6, pp. 375–396*).—Chemical analyses of several samples of soils from different parts of São Paulo are reported, with suggestions as to the fertilizers suitable to each.

The decomposition of organic substances and the forms of humus in their relations with agriculture, E. WOLLNY (*Ann. Sci. Agron., 1898, II, p. 339; 1899, I, No. 2, pp. 208–286, figs. 43; II, Nos. 1, pp. 1–116, figs. 2; 2, pp. 260–299, figs. 3; 3, pp. 362–439; 1900, I, No. 1, pp. 1–29*).—See E. S. R., 8, p. 879.

A contribution to the knowledge of soil bacteria, R. KOLKWITZ (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 20, pp. 670–678, pl. 1*).—Studies are given on the Alinit bacillus (*B. ellenbachensis*) and other soil organisms.

Green manures, TRABUT (*Gouv. Gen. Algeria, Serv. Bot., Sta. Exp. Rouiba Bul. 20, 1899, pp. 24, figs. 15*).—A brief discussion of the principles of green manuring and of the value for this purpose of various plants tested at the station of Rouïba, Algeria. The plants discussed include 4 species of lupines, fenugreek, beans, vetches, 4 species of Lathyrus, melilotus, lentils, serradella, sulla and other species of Hedysarum, galega, 2 species of Mucuna, including velvet bean (*Mucuna utilis*), cow peas, soy beans, and *Madia sativa*.

The fertilizing value of lupines at different stages of growth, HEINRICH (*Fühling's Landw. Ztg., 49 (1900), Nos. 2, pp. 61–67; 3, pp. 90–94*).—Plat and pot experiments are reported in detail, which lead to the conclusion that the best results as green manure will be obtained by turning under the lupines when they begin to ripen and less than half of their leaves have become yellow, because at this stage the plant has reached the limit of production.

History and present status of Peruvian guano, MAIZIÈRES (*L'Engrais, 15 (1900), No. 4, pp. 83–85*).—The history of the exploitation of the Peruvian deposits of guano is briefly reviewed and statistics of their present extent and exportation are given.

Fertilizer inspection in 1898, C. D. WOODS (*Maine Sta. Rpt. 1898, pp. 38–47*).—The requirements of the State fertilizer law are briefly explained, and the composition of samples of fertilizers collected by the station is compared with that of samples furnished by the manufacturers and with the guaranteed analyses for 1898 and for the three years 1896–1898. See also Bulletins 43 and 45 of the station (E. S. R., 10, pp. 387, 734).

Report of analyses of commercial fertilizers for the spring of 1899, L. L. VAN SLYKE (*New York State Sta. Bul. 160, pp. 63–151*).—The results of analyses of 646 different brands of fertilizers are reported. Of these 482 were complete fertilizers in which the nitrogen varied from 0.37 to 8.5 per cent, averaging 2.01 per cent. The available phosphoric acid varied from 1.2 to 15.12 per cent, averaging 8.76 per cent. The potash varied from 0.43 to 12.95 per cent, averaging 4.86 per cent. The average amounts of nitrogen, available phosphoric acid, and potash exceeded the guaranteed average by 0.15, 0.98, and 0.3 per cent, respectively. The bulletin also gives the text of the State fertilizer law as amended in 1899. The amended law requires a license fee of $20 for each brand.

Analyses of commercial fertilizers, T. J. EDGE and W. FREAR (*Pennsylvania Dept. Agr. Bul. 44, pp. 62*).—Includes text of the State fertilizer law, notes on the valuation of fertilizers, and tabulated analyses and valuations of 945 samples examined during 1898. This is reprinted in the Pennsylvania Department of Agriculture Report for 1898, pt. 1, p. 805.

Miscellaneous analyses, H. J. WHEELER (*Rhode Island Sta. Rpt. 1898, pp. 117–121*).—Analyses (mainly fertilizing constituents) are reported of cotton-seed meal, refuse from indigo dye vats, Belgian phosphate, "floats" (finely ground mineral phosphate), steamed bone, dissolved bone, superphosphate, tankage, dried blood, nitrate of soda, sulphate of ammonia, nitrate of potash, potassium carbonate, muriate of potash, sodium carbonate, common salt, and burnt lime.

The production and consumption of phosphatic slag in Europe, MAIZIÈRES (*L'Engrais, 15 (1900), No. 6, pp. 132–134*).—The total production in Europe is stated to be 1,416,000 tons (metric), the greatest producer being Germany, 786,000 tons. The consumption in the countries manufacturing the product is placed at 1,208,000 tons; the exports, mainly to Italy, Russia, Holland, Switzerland, Norway and Sweden, Australia, and other countries, at 208,000 tons.

The injurious effect of perchlorate in nitrate of soda, J. STOKLASA (*Bl. Zuckerrübenbau, 7 (1900), No. 2, pp. 17–28; Böhm. Ztschr. Zuckerind., 24 (1899), p. 131*).—According to the author's experiments the limit of endurance of rye for perchlorate is 1 per cent, for oats 1.5 per cent, and for wheat, barley, and beets 2 per cent. Beets are especially resistant to perchlorate. Of 200 samples of nitrate of soda examined, 132 contained less than 1 per cent of potassium perchlorate; 40 contained 1 to 1.5 per cent; 20, 1.5 to 2 per cent; 6, 2 to 3 per cent, and 2, 3 to 7 per cent.

A further study of the lime requirement of Rhode Island soils, H. J. WHEELER and G. E. ADAMS (*Rhode Island Sta. Rpt. 1898, pp. 171–179, pls. 4*).—This is an account of cooperative experiments in 8 different localities in the State during 1898 in continuation of work of previous years (E. S. R., 10, p. 938). "The experiments of this season fully confirm the opinion that a need of lime is much more universal in Rhode Island than has been generally supposed."

FIELD CROPS.

A chemical study of the sea-island cotton plant, F. S. SHIVER (*South Carolina Sta. Bul. 47, pp. 102, fig. 1*).—Preliminary to the chemical work of this bulletin, the author gives a general discussion of the origin of sea-island cotton, its history in South Carolina, production, uses, culture, character, and appearance; describes the character of sea-island cotton soils, and the method of preparing lint, and gives data showing the cost of production and profit in growing per acre.

The analytical data show the food and fertilizing constituents of the whole plant and of each individual part. The finest and coarsest samples of the sea-island cotton crops of 1896 and 1898 were used in the analyses. The data obtained are compared with similar data obtained in the analysis of upland cotton. The following table shows the average analysis of different parts of the 1896 and 1898 crops of finest and coarsest sea-island cotton with reference to fertilizing constituents:

On the basis of the proportionate parts of the plant, it is calculated that a crop of the finest sea-island cotton, yielding 200 lbs. of lint per acre would produce 507 lbs. of seed, 620 lbs. of bolls, 1,137 lbs. of leaves, 1,834 lbs. of stems, and 640 lbs. of roots, or a total crop of 4,938 lbs. (air-dry). In round numbers, this crop would remove from the soil 68.5 lbs. of nitrogen, 36.6 lbs. of phosphoric acid, and 89.4 lbs. of potash. The number of plants per acre for this crop is estimated at 7,079. By the same method of calculation, a crop of the coarsest variety of sea-island cotton, yielding 200 lbs. of lint per acre, would produce 411 lbs. of seed, 384 lbs. of bolls, 439 lbs. of leaves, 1,192 lbs. of stems, and 427 lbs. of roots, or a total crop of 3,053 lbs., which is nearly a ton less than the total yield of an acre of the finest sea-island cotton. The amount of fertilizing constituents removed by this crop is calculated, in round numbers, at 42 lbs. of nitrogen, 18 lbs. of phosphoric acid, and 43 lbs. of potash. The number of plants per acre is estimated at 3,555.

The author averages the results of these 2 crops and concludes that an average crop of sea-island cotton would have a total weight of 3,683 lbs. and contain 4,734 plants to the acre. This crop would contain in round numbers 51 lbs. of nitrogen, 58 lbs. of potash, and 24 lbs. of phosphoric acid.

In the light of this data the author critically discusses present methods followed by many planters in fertilizing cotton, and suggests methods for improving the fertilizer formulas. The whole matter is summarized in tabular form. The data show that in practice on an average 60 lbs. of phosphoric acid, 45 lbs. of nitrogen, and 49 lbs. of potash are applied per acre by the best planters. A fertilizer composed of 4 per cent available phosphoric acid, 7 per cent nitrogen, and 8 per cent potash, applied at the rate of 750 lbs. per acre, would just about restore to the soil the amount of fertilizing elements removed by an average crop of sea-island cotton yielding 200 lbs. of lint per acre. The use of marsh mud as a fertilizer for cotton is especially noted, and analyses given of 2 samples.

The exhaustive effect of growing sea-island cotton when both lint and seed are entirely removed from the land is considered. The removal of the lint alone is an item of minor importance, and even when the seed is also removed, the amount of fertilizing constituents taken from the soil is less than half that removed by crops of 30 bu. of wheat or 20 bu. of corn. There is a close agreement between the amount of plant food removed by a crop of sea-island cotton and that removed by upland cotton, with the difference slightly in favor of the sea-island cotton.

The analyses with reference to food constituents of lint, seed, bolls, leaves, stems, and refuse of the 1896 and 1898 crops of coarsest and finest sea-island cotton is shown in the following table:

Average analyses of the parts of the plant of the finest and coarsest varieties of sea-island cotton.

The food composition of the whole plant was determined by grinding together the different parts and incorporating the lint with the mixture.

The food constituents of the different parts of the plant are considered of little value unless ground and mixed with meal or grain or with some succulent food, as corn silage. Under such conditions the plant would compare favorably in feeding value with meadow hay.

In conclusion the analyses are compared with those of Jackson, Ure, and Wohltmann, and with the analyses of upland cotton by McBryde (E. S. R., 3, p. 537). The upland cotton has the larger stem and root development. The absolute amount of lint and seed produced on an acre is about the same in both cases, but the upland cotton requires a larger amount of fertilizer. The seed of the sea island cotton is much richer in fertilizing constituents, and is considered superior to upland cotton seed for feeding purposes, although somewhat poorer in fat and fiber.

Relative effects on cotton and corn of certain leguminous crops turned under entire and their stubble only turned under, R. L. BENNETT (*Arkansas Sta. Bul. 58, pp. 106, 107*).—Cowpeas, soy beans, and velvet beans were grown under uniform conditions and half of each plat cut and removed for hay. The entire plats were plowed under in the fall. Cotton was planted on the different plats the following spring. The largest yield of seed cotton per acre was obtained from the plat where the vines and stubble of velvet beans had been turned under. The yields were considerably reduced when the vines were cut for hay and the hay removed. In a similar experiment with corn the best yield was obtained on the plat where soy-bean vines and stubble had been turned under, followed by the plat on which cowpea vines had been turned under. Velvet beans were not used in the experiment with corn. The author notes that "the value of the hay cut from the 2 stubble plats was worth more than the increase of corn and cotton on plats where the vines were turned under for manure."

Winter pasturage, hay, and fertility afforded by hairy vetch, J. F. DUGGAR (*Alabama College Sta. Bul. 105, pp. 129-160*).—This bulletin gives in detail methods of growing, inoculating, and fertilizing hairy vetch (*Vicia villosa*), and considers its adaptability as winter pasturage and green-manure crop for the South. Earlier work with this plant at the station has been reported (E. S. R., 10, p. 837).

Hairy vetch is considered an especially valuable forage plant for the South, as its culture does not in any way interfere with the regular farm crops, and it is valuable either as pasturage, hay, or for use as a green-manure crop. Sown in September or October, alone or with oats, it furnishes pasturage during the following February, March, April, and May, and, if not grazed too late, it affords a cutting of hay from April 20 to May 10. Its growth during the winter months serves to prevent leaching of the soils, and adds greatly to the supply of soil nitrogen, Specific directions are given for securing the growth of the plant, on land where it has not been previously grown, by the aid of Nitragin, inoculations from old hairy vetch or English pea fields, and inoculation by replanting on the same land.

A special study was made at the station of the most suitable time for cutting hairy vetch for hay and for using as a green manure. The following table shows the yield and composition of the crop when cut at different dates for hay:

Yield and composition of hairy vetch cut at different dates.

Date.	Stage of growth.	Hay.	Composition.					
		Yield per acre.	Moisture.	Crude protein.	Carbohydrates.	Fat.	Crude fiber.	Ash.
		Lbs	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Apr. 19	Just before blooming	3,117	20.72	23.45	26.25	2.22	20.24	[illegible].12
Apr. 26	5 per cent of blooms showing	3,705	22.83	18.97	29.06	2.11	20.44	[illegible].59
May 2	In full bloom	5,789	20.30	17.15	32.12	2.14	22.50	5.[illegible]9
May 9	Seed pods formed but not filled	5,463	22.48	18.71	29.50	2.35	19.92	7.04

"The percentage of protein (muscle formers) in vetch hay is higher than in other leguminous hays, as red clover and cowpea vines, which are usually taken as standards in this respect, and much higher than in corn blades or 'fodder.' Vetch hay contains 3 times as much of these 'muscle formers' as Johnson grass hay."

In order to determine the fertilizing value of hairy vetch at different stages of growth, samples of vines, stubble, and roots were taken at different dates and analyzed. The roots were taken to a depth of 6 in. and were attached to stubble 2 or 3 in. long. The data obtained are summarized in the following table:

Analyses of vines, roots, and stubble of hairy vetch at different stages of growth.

Date.	Stage of growth.	Air-dry material per acre.	Fertilizing materials.		
			Nitrogen.	Phosphoric acid.	Potash.
Apr 19	Just before bloom:	*Pounds.*	*Per cent.*	*Per cent.*	*Per cent.*
	Vines	3,117	3.75	0.81	2.18
	Roots and stubble	850	2.36	.49	1.23
Apr 26	5 per cent of blooms showing				
	Vines	3,705	3.03	.78	2.14
	Roots and stubble	870	2.03	.48	.88
May 2	In full bloom				
	Vines	5,789	2.75	.79	2.21
	Roots and stubble	1,054	1.97	.48	.88
May 9	Seed pods formed, but not filled:				
	Vines	5,463	2.99	.74	2.68
	Roots alone	346	2.19	.43	.96
	Stubble, fallen leaves, and blooms	1,061	2.07	.42	1.14

It is calculated that the nitrogen contained in the vines, stubble, and roots from an acre harvested when the plant was in full bloom, May 2, would be equivalent to the nitrogen contained in 2,571 lbs. of cotton-seed meal, and that one week later it would be equivalent to 2,896 lbs. of cotton-seed meal. The total nitrogen content of the crop increases with the stage of maturity. This suggests the advisability of postponing plowing-under the crop for green manure until as late in the life of the plant as practicable.

A brief account is given of experiments in growing corn on plats where either the entire growth of vetch, the stubble of vetch, or the entire growth of nearly matured rye or the stubble of rye, had been plowed under. "The yield of corn in 1898 was at least 50 per cent, and in some instances 100 per cent, greater on the plats where vetch or vetch stubble had been plowed in than on the plats where rye had grown."

There was but little difference in the yield of grain, whether the entire vetch plant or only the stubble and roots were plowed under. When silage corn was grown the yield per acre on the vetch stubble plat was 2.75 tons less than on the plat where vetch vines, stubble, and roots had been plowed under.

"This superior yield of silage corn resulting from plowing in the entire growth of vetch was more than offset by the 3,600 lbs. of hay per acre obtained from the vetch stubble plat. This contained a greater amount of dry matter of better quality than that in the 2.75 tons of silage corn."

Directions for sowing hairy vetch, fertilizing, reseeding, and adapting to ordinary rotations are considered in some detail, and mention made of the enemies of vetch and the possibility of the plant becoming a weed.

The water requirements of the oat plant under different conditions of soil moisture and of manuring, C. VON SEELHORST (*Jour. Landw., 47 (1899), No. 4, pp. 369–378*).—Experiments were made with oats to ascertain whether the quantity of water required to produce a given amount of dry matter is determined exclusively by the growth of the plant, or whether the composition of the fertilizers applied is also concerned in it. It was concluded from the experiments that in general the quantity of water required to produce a unit of dry matter decreases as the luxuriance of growth increases. It was also concluded that the water requirement is influenced by the relative amount of each fertilizer element supplied, and that too heavy an application of a single element, even though it results in little or no increase in yield, nevertheless increases the water requirement of the plant. The experiments appear to indicate that the composition of the soil exercises much influence on water requirement.

The practical value of these results, it is stated, lies in the demonstration of the fact that up to a certain point the more nearly complete the fertilizer applied, the more fully may the soil water be utilized; but if the water content of the soil is too low the concentration of the solutions in the soil, such as would follow a heavy application of fertilizer, have an injurious effect on growth.

Planting unshelled peanuts, R. L. BENNETT (*Arkansas Sta. Bul. 58, pp. 102, 103*).—A comparison was made of growing peanuts from shelled, unshelled, and broken seed. The unshelled peanuts were prepared by placing a small quantity of nuts in a sack and immersing in water for 12 hours to thoroughly wet the hulls, after which the sacks were buried in the earth below frost line. Peanuts were thus treated January 1, February 1, March 1, and April 1. They remained in the ground until April 23, when they were taken up and planted. On the same date plantings were made of shelled nuts, of dried unshelled nuts and of nuts with pods broken into two parts. The percentage growth of the different lots of seed is tabulated. The most perfect stand (95.1 per cent) was obtained from the nuts planted in broken pods. The shelled nuts stood second (94.8 per cent) and the unshelled nuts buried in the earth April 1, third (92.5 per cent). None of the unshelled pea nuts buried in the earth January 1 grew. The results seemed to indicate that when nuts have been thoroughly wet and kept moist for a short period they will produce a good stand. This saves the expense of shelling the peanuts by hand.

Trials of varieties of potatoes, J. A. TILLINGHAST and H. J. WHEELER (*Rhode Island Sta. Rpt. 1898, pp. 180–185*).—Eighteen varieties of field potatoes and 4 varieties of German salad potatoes were grown. Early Michigan gave the largest yield of tubers among the early varieties tested, 255.2 bu. per acre. The best total yield of all the varieties tested was made by the Prof. Maercker, 399.8 bu. per acre.

The German salad potatoes were compared in a cooking test with tubers of the New Queen variety for salad purposes. The German potatoes held their form well and "proved superior in every respect for salad purposes." Descriptive notes are given on 11 of the varieties tested.

Field experiments with fertilizers on tobacco; influence upon yield, W. FREAR (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 662–676*).—A summary is given of the cooperative tobacco fertilizer experiments begun by the station in 1893 (E. S. R., 7, pp. 762, 947), and including the results in 1897. The general purpose of these experiments has been "(1) to compare stable manure with artificial fertilizers rich in humus-making ingredients; (2) to determine the influence of the kind of material used to supply the fertilizer elements upon the yield and quality of tobacco leaf, the quantities of nitrogen, potash, and phosphoric acid being the same in each artificial combination; and (3) to determine the need for soluble phosphates in addition to those present in the humus-making ingredients of the artificial fertilizers. Treatment as regards culture, curing, and sorting was the same throughout."

Each of the principal fertilizer formulas employed contained similar amounts of the 3 essential elements, viz, 95 lbs. of nitrogen and 155 lbs. each of potash and phosphoric acid per acre.

> "The experiments were conducted in Donegal (Marietta), (1893–1897), and at Rocky Spring (Lancaster), (1893–1895), in Lancaster County, and at Ulster (1895) and Wysox (1896–97), Bradford County. The Lancaster County stations were upon typical limestone-clay soil of that tobacco region, the soil being moderately supplied with humus and lime, rich in magnesia, iron, and alumina, and well supplied with potash, but rather deficient in nitrogen, and that at Donegal in phosphoric acid. The Wysox alluvium was sandy and contained nearly as much iron, lime, and phosphoric acid as the Rocky Spring soil, but less nitrogen, magnesia, and sulphuric acid."

The yields of tobacco obtained per acre with the different combinations and amounts of fertilizers in the various localities are tabulated for the different years. The author summarizes the results obtained as regards the yield of leaf as follows:

"With a single season excepted (Wysox, 1897), stable manure was surpassed, at all places and in all seasons, by artificial fertilizers rich in humus-making materials, such as cotton seed or linseed meal, their yield being from 3 to 15 per cent greater than by stable manure.

"Linseed meal, used only at Donegal, was never superior and sometimes inferior to the less expensive cotton-seed meal.

"Horn meal was quite inferior, at first, to cotton-seed meal; but as its residual effect accumulated and as it was aided by later moist seasons, the inferiority diminished.

"Wheat bran gave excellent results during the single season of its trial, but the conditions of test do not permit comparison with the other similar substances used in these experiments.

"The partial substitution of nitrate of soda for cotton-seed meal resulted in a larger yield only in the dry seasons on the clay soil; in other seasons, in a considerable diminution of crop, not to mention the inferiority shown in the field appearance of the leaf produced. At Ulster it caused an increase of yield.

"The similar substitution of sulphate of ammonia was productive of a very marked gain at Donegal, though this varied in different seasons. There was more variation on the alluvial soil, but the results were in general favorable to this substitution. At Donegal the average for the years 1894–1897, this treatment not having been started in 1893, shows an increase of 120 lbs. of leaf per acre as the result of this substitution.

"The double carbonate of magnesia and potash produced a plant of excellent quality, and the average yield was materially improved. The superior excellence of result was more notable in dry seasons than in moist, and was observed both on the clay soils and the alluvium. The most marked peculiarity of the crops produced by the mixture containing this ingredient was the uniformly fine quality of the leaf both in dry and wet seasons.

"The use of wood ashes was not a part of the original plan of the experiment. When used it was applied alone in large quantity to a plat that had in preceding years received stable manure only. The result was not favorable in any respect. This affords, however, no indication of the value of wood ashes when used in mixture as the sulphate and double carbonate of potash were used.

"The use of soluble phosphoric acid in greater or smaller quantity on soils upon which tobacco is grown continuously is necessary, though in a dry season, before the land has been long used for this crop, the addition of soluble phosphoric acid in considerable quantities may reduce the yield. At Donegal, notwithstanding the large excess used each year, the beneficial results of each application remained clearly marked. The alluvial soils of Bradford County exhibited less need for this material. It is probable that on the Bradford alluvial soil tobacco fertilizers should be used that contain less soluble phosphoric acid than is commonly found in commercial grades of fertilizer now offered on the market.

"The phosphoric acid in basic slag phosphate has proven rapidly enough available on the average arable soil to produce many vegetables and spring grains; it has, in these experiments with tobacco, given a marked increase in yield, but considerably less than the same weight of phosphoric acid used in the form of an acidulated phosphate."

Tests of fertilizers on wheat, D. O. Nourse (*Virginia Sta. Bul. 93, pp. 111–116, dgms. 3*).—These tests were begun in 1896. The results for the years 1896–1898, inclusive, have been previously noted and the general plan of the experiment described (E. S. R., 10, p. 1037). The present bulletin gives the results obtained in 1890 and compares them with those obtained in previous years. The average yields for the year show but little more than half a crop, but the relative effects of the different fertilizers accord entirely with the results obtained in previous years; *i. e.*, the greatest yields of both grain and straw have been produced on plats fertilized with all three essential elements, and the most effective of these elements has been phosphoric acid. Considered from a financial standpoint the results obtained for the whole 4 years of the test show that nitrogen and potash used alone or combined on the station soils have regularly resulted in loss. Phosphoric acid alone has proven more profitable than applications of potash, phosphoric acid, and nitrogen combined, though the yield per acre has been a little less. The greatest profit resulted from the combined use of phosphoric acid and potash.

Electricity in agriculture, G. S. HULL (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 626–635*).—An historical summarization of experiments made with electricity in the culture of certain plants, with suggestions as to its further use in agriculture.

History of the practice of catch-cropping, P. HABERNEL (*Mitt. Landw. Inst. K. Univ. Breslau, 1899, No. 2, pp. 44*).—The author places the origin of the practice of catch-cropping in the period of the improved 3-year rotation. When the practice was introduced of growing an early-maturing crop in the first year of the rotation instead of allowing the land to lie fallow, we find the beginning of the culture of catch crops. The history of this practice of growing intermediate crops is reviewed, and the impetus given by Hellriegel's discovery of nitrogen assimilation and the present difficulties in the way of a more general culture of legumes are discussed. The problems in this connection which need investigation are the relations of climate and soil to legumes grown especially as catch crops, comparative tests of species grown for this purpose, and methods of utilizing the product. The article is accompanied by bibliographical references.

Some suggestions in the use of fertilizers, C. E. THORNE (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 596–615*).—A suggestive popular article.

Relative effects of cotton meal, whole and crushed seed on the yield of corn, cotton, and potatoes, R. L. BENNETT (*Arkansas Sta. Bul. 58, pp. 104, 105*).—In these trials the relative effects of the different fertilizers on the long-growing crops, corn and cotton, were about the same, while on potatoes the advantage lay with the cotton-seed meal for the apparent reason that it was more readily available.

Economic value of maize, R. LOPEZ Y PARRA (*Bol. Red.Met. y Rev. Cient. México, 2 (1898), No. 10, pp. 107–109*).

Alfalfa in eastern Kansas, H. M. COTTRELL (*Kansas Sta. Press Bul. 51, p. 1*).—Notes on the nature and value of alfalfa as a farm crop in eastern Kansas.

Awnless brome grass (*Kansas Sta. Press Bul. 47, p. 1*).—Notes on the nature of this plant (*Bromus inermis*) and on its adaptability to Kansas.

Allen Hybrid cotton, R. L. BENNETT (*Arkansas Sta. Bul. 58, pp. 107, 108*).—This variety of cotton was compared with the variety Eldorado. "The Eldorado grows a little larger and has larger and less pointed bolls. The fiber of the Allen Hybrid is more silky and finer to the touch than Eldorado, but the latter is more productive and better for general cultivation."

Crimson clover, T. A. WILLIAMS (*U. S. Dept. Agr., Division of Agrostology Circ. 17, pp. 6, fig. 1*).—Popular directions for the culture of crimson clover (*Trifolium incarnatum*), with notes on its uses as hay and for soiling, pasturage, silage, green manure, and a soil cover. The plant is described and its conditions of growth given. Crimson clover "is too tender for successful general cultivation outside of the Middle and South Atlantic and Gulf States." It "has a high feeding and fertilizing value [illegible] best crops that can be grown in short rotations for forage and soil [illegible] . . . The seed should be sown in late summer or early autumn at the [illegible] 10 to 20 lbs. per acre on a well-prepared seed bed. . . . The crop should [illegible] at or before full bloom and for seed as soon as ripe; in the latter case [illegible] threshed or put under cover as soon as dry."

[illegible] leguminous forage plants, A. S. HITCHCOCK (*Kansas Sta. Press Bul. 52, p. 1*).—[illegible] clover, alfalfa, and soy beans are considered the most desirable legumes for [illegible] in Kansas. Notes are given on these and other forage plants and their [illegible] compared.

Grasses and forage plants. Part I, Domesticated grasses, J. B. KILLEBREW (*Tennessee Sta. Bul. Vol. XI, No. 2, pp. 72, pls. 2, figs. 40*).—Illustrated descriptions are given of 29 domesticated grasses growing in the vicinity of the station with cultural notes in each instance, and information regarding harvesting, marketing, and uses.

Grasses and forage plants. Part II, Domesticated leguminous plants, J. B. KILLEBREW (*Tennessee Sta. Bul. Vol. XI, No. 3, pp. 73–111, figs. 8*).—Popular cultural notes on 12 of the more important leguminous plants grown for forage in Tennessee.

Grasses and forage plants. Part III, Meadows and wild pastures, J. B. KILLEBREW (*Tennessee Sta. Bul. Vol. XI, No. 4, pp. 113–144, figs. 20*).—Popular directions for the establishment, care, and management of meadows in Tennessee, with formulas for mixing grass seed for planting lawns, orchards, and permanent pastures on different soils, and notes on some of the highway and mountain pastures of the State.

Influence of water and soil nutrients on the growth of potatoes, J. WILMS (*Jour. Landw., 47 (1899), No. 3, pp. 251–292, pls. 3*).

Yield of Spanish peanuts planted at different distances, R. L. BENNETT (*Arkansas Sta. Bul. 58, pp. 101, 102*).—Spanish peanuts were grown in rows 2 and 3 ft. apart, respectively, with hills 4, 6, 8, 12, and 18 in. distant in the row. The yields are tabulated. When the rows were 2 ft. apart, the yields averaged 140 bu. per acre annually; when 3 ft. apart, 109 bu. per acre. For the station soils, rows 2½ ft. apart are suggested, with hills 8 to 9 in. distant in the row.

Saltbushes, P. B. KENNEDY (*U. S. Dept. Agr., Farmers' Bul. 108, pp. 19, figs. 9*).—Notes are given on the general characteristics of saltbushes; on the distribution of saltbush seed by this Department, and on methods of growing the plants. Descriptions of 6 introduced and 6 native saltbushes of agricultural importance, and compiled data as to the feeding and fertilizing value of saltbushes make up the larger part of the bulletin. Several miscellaneous plants grown on alkali soils are also described and brief notes given on the characteristics of alkali soils.

Soy beans (*Kansas Sta. Press Bul. 46, p. 1*).—The planting, cultivation, and harvesting of soy beans are briefly discussed, as well as the cost of production, feeding value, and resistance to drought.

Experiments with sugar beets in 1899 and 1900, J. T. WILLARD (*Kansas Sta. Press Bul. 53, p. 1*).—"The results of the past 3 years confirm those of former years and indicate that while Kansas has produced many individual plants of excellent quality she has produced more of inferior quality, and that States in higher latitudes are better situated for successful sugar beet production." The samples grown within the State in 1899 averaged from 10.89 to 11.49 per cent of sugar in the beet with an average purity coefficient of from 73 to 75 per cent.

A further contribution to the knowledge of the tobacco plant, J. BEHRENS (*Landw. Vers. Stat., 52 (1899), No. 5–6, pp. 431–454*).—Includes a botanical and chemical study of the color of tobacco; inconclusive results of investigations relative to the cause of the blast ("mauche," "mauke") of tobacco, a disease similar in character to the mosaic disease of tobacco; and an account of experiments in breeding tobacco.

The growing and curing of wrapper leaf tobacco in New England and elsewhere, E. H. JENKINS (*Connecticut State Bd. Agr. Rpt. 1898, pp. 89–112*).

HORTICULTURE.

Horticultural division, F. W. CARD (*Rhode Island Sta. Rpt. 1898, pp. 106–110, pls. 7*).—Notes are given on some results in growing Longfellow flint corn in close proximity to sweet corn, on cross fertilizing watermelons, and on the root and top pruning of apple trees at the time of planting. In the experiments with corn "careful observations at husking time failed to show any kernels of the sweet corn type on the ears of the flint corn, though the yellow kernels were very numerous on sweet corn ears, being most abundant on ears taken from rows next the yellow corn." No influence on the color of the flesh resulting from crossing yellow and red-fleshed watermelons was observable.

The experiment in top and root pruning trees was carried out with two-year-old stock of the Northern Spy variety. Ten trees were treated in each of the following ways: (1) Two-year whips, (2) limbed trees pruned to a whip when set, (3) branches cut back one-half, leader left, (4) untrimmed, (5) roots untrimmed, (6) roots cut back one-half, (7) cut back closely, (8) Stringfellow method—roots cut back to a mere stump 1 or 2 in. long and the tree to a trunk about a foot high. Notes on the growth of the different lots are given. The methods of pruning and the root and top development of representative specimens are illustrated by photographs. All the trees made good growth, but the best results were obtained when all sound roots were left undisturbed.

Experiments in progress are noted in outline.

A comparison of large and small radish seed, W. M. MUNSON and L. J. SHEPARD (*Maine Sta. Rpt. 1898, pp. 158–160*).—Studies by E. R. Mansfield on the influence of the size of seed upon germination are reported. Comparisons were made of the yield of radishes from large and small seeds. In the first trial the number of first-class roots from 100 uniformly large seeds was about 30 per cent greater than the number from 100 uniformly small seeds, while the weight of the former crop exceeded the latter by about one-third. In a second trial, 300 seeds weighing 4.19 gm. produced 63 per cent of strictly first class roots, while the same number of seeds, weighing only 1.78 gm., produced only 13 per cent of the same grade of roots. In a third trial the number of first class roots produced by 200 seeds, weighing 2.8 gm., exceeded the number produced by 200 seeds, weighing only 1.2 gm., by about 28 per cent. In weight about the same difference was obtained. The conclusions drawn from the observations are stated as follows:

> "It is evident that plants from large seed grow larger and mature earlier than those from small seed. Inasmuch as the cost of seed is slight as compared with the cost of labor and fuel, and in view of the importance of having the crop ready for market in the shortest possible time, the gardener can well afford to sift the seed before planting and discard all which is small and inferior. For the purpose of sifting, common wire cloth which is used for window screens ($\frac{1}{12}$-inch mesh) will answer, though a screen with $\frac{1}{16}$-inch mesh is better, as many of the small seeds will not readily pass through the window screen."

The effect of subwatering radishes, W. M. MUNSON and L. J. SHEPARD (*Maine Sta. Rpt. 1898, pp. 161–163, pl. 1*).—An account of the experience of the authors in growing radishes, in which the yield from subwatered and surface-watered benches was compared. In one trial "the plants which were subwatered were superior to the others from the beginning. At the time of harvesting the number of first-class roots on the subwatered section exceeded that on the surface-watered section by [illegible] per cent, while the average weight was 14.5 per cent greater." In a second trial the advantages of subwatering as compared with surface-watering were demonstrated on a commercial scale. There was little difference in germination in the 2 lots, but very many more plants were lost by damping off on the surface-watered section than on the other.

> "The subwatered section yielded twice as many bunches of marketable roots as did the other. The percentage of marketable roots was much higher and the average size greater from the subwatered section. The difference in the yield of the two sections was more than enough to make the difference between profit and loss in growing the crop. . . . More than half of the roots [from the subwatered section] were classified as 'second-class and culls.' It should be said in explanation that about half of the number so classed were simply of small size; many of them were inferior or diseased; others were of good size and quality, but badly disfigured by attacks of millipedes.
>
> "The number of roots attacked by millipedes was much greater on the subwatered section—a significant fact in connection with the control of this pest. The number of diseased and inferior roots was much larger on the surface-watered section. This, together with the fact previously noted, that there was much more trouble from 'damping off' on this section, is also significant. The injured roots were mostly of marketable size, but deformed."

Fruits of Oklahoma, O. M. MORRIS (*Oklahoma Sta. Bul. 13, pp. 12*).—An account, based on the reports of 37 growers, is given of the different varieties of orchard and small fruits most successfully grown in different parts of the Territory. Orchards and vineyards located on the richer bottom lands have generally given better results than on uplands, though upland orchards usually come into earlier bearing. Apples, plums, pears, peaches, and grapes have been grown successfully in nearly all portions of the Territory. Sweet cherries succeed with difficulty but sour varieties have been successfully grown on nearly all soils. Blackberries, apricots, currants, and raspberries have been only partially successful. Lists of favorite varieties of the different orchard and small fruits for both commercial and home orchards are given, and suggestions added regarding desirable shade trees and methods of planting them.

Peach culture in Canada, J. CRAIG (*Canada Cent. Expt. Farm Bul. 1, 2. ser., pp. 45, figs. 19*).—This is a manual of peach culture as adapted to local conditions in Canada. A summarized statement is made of the experience and practice of a number of growers in Ontario. Notes are given on peach yellows, leaf curl, fruit rot, mildew, black spot, root galls, borer, curculio, and aphis. An unidentified and apparently contagious disease of the peach which has appeared in orchards in Ontario is characterized. A preliminary study was made of the relative hardiness of the fruit buds of different varieties. A list of varieties, in the order of hardiness, is tentatively submitted as follows: Hill Chili, Longhurst, Barnard, Early Rivers, Salway, Smock, Tyhurst, Wager, Yellow St. John, Amsden June, Hyne Surprise, Hale Early, Fitzgerald, Foster, Reeves Favorite, Crawford Late, Crawford Early, Wheatland, Mountain Rose, Early Richmond, Red Cheek Melocoton, Old Mixon, Alexander, Early York, Garfield, Champion, Shaw Rareripe, and Stephen Rareripe.

Effects of the February freeze of 1899 upon nurseries and fruit plantations in the Northwest, E. S. GOFF (*Wisconsin Sta. Bul. 77, pp. 18, figs. 2*).—A circular letter of inquiry requesting information as to the injuries to fruit trees caused by the February freeze of 1899 was sent to fruit growers and nurserymen in Wisconsin, Minnesota, Iowa, the Dakotas, and Manitoba. More than 100 replies were received, and extracts from these are given in notes and tables. The lowest temperature recorded was —52° F. Nursery apple stock least injured by the freeze was Duchess of Oldenburg. Hibernal, Wealthy, and Whitney No. 20, in the order named. Twenty-three correspondents reported Wealthy least injured in the orchard, 21 Duchess of Oldenburg, 9 Yellow Transparent, and 6 Hibernal. Fifty-seven correspondents reported that the ground was destitute of snow at the time of the freeze, and of this number 43 stated that "the principal damage to nursery and orchard trees was to the root, while only 3 thought the damage greater in the tops than in the roots." Of the 34 correspondents who reported the ground covered with snow, "20 reported that the injury was chiefly in the top and 6 stated expressly that there was no root injury." Crabs were less injured than common apples, and this fact suggests the advisability of using crab roots for stock in the Northwest.

The blossom buds of 18 varieties of cherries at the station which had been exposed to a minimum temperature of —27.5° F. were examined. The results which are tabulated show the percentage of live buds to vary from 5.7 in the case of Bessarabian to 98.5 in the case of the large Morello. Relative to plums the author states that "the Japanese plums appear to have suffered more, as a rule, than the European. The Chicasaw plums appear to have suffered nearly as much as the European, but the American class have vindicated their claim to perfect hardiness so far as their flower buds are concerned. The young trees, however, while they have perhaps endured better than those of any other fruit, have not been wholly exempt from root killing."

The Loudon red raspberry "seems to have endured the conditions better than most other red varieties." Several red varieties are reported to have endured a temperature of —50° F. at Manitoba without protection. Of the Black Caps the Older proved to be most hardy. Blackberries, generally, suffered severely. "The Snyder blackberry demonstrated its superior hardiness in many cases."

The results of the injuries suggest the value of a snow covering for nursery stock; and to this end it is advised that nurseries be planted, so far as practicable, on north slopes, and the nursery blocks interspersed with evergreen wind-breaks extending east and west. Next in value to a snow covering is a covering of litter. Oats, buckwheat, peas, vetches, or mammoth clover are advised as catch crops for this purpose. Mammoth clover is advised only in wet seasons. It is thought by the author that "had the crab been generally used for root grafting the apple in the Northwest, the loss from root killing would have been reduced at least one-half." Plums should be worked on American seedlings and the cherry on the Mahaleb stock.

The blueberry in Maine, W. M. MUNSON (*Maine Sta. Rpt. 1898, pp. 164–172, figs. 5*).—An account is given of the blueberry industry in Maine, with botanical descriptions of the dwarf or low-bush blueberry (*Vaccinium pennsylvanicum*), low black blueberry (*V. nigrum*), velvet leaf or "sour top" (*V. canadense*), and high-bush blueberry (*V. corymbosum*). Culture experiments with blueberries by horticulturists in Massachusetts are reported.

> "In New England the term 'blueberry' is applied indiscriminately to various species of Vaccinium, particularly to *V. pennsylvanicum*, *V. vacillans*, and *V. canadense*. *V. corymbosum* is known as the high-bush blueberry.
>
> "The species most commonly found are, in the order of their commercial importance, *V. pennsylvanicum*, *V. canadense*, *V. corymbosum*, *V. nigrum*, and *V. vacillans*.
>
> "The 'blueberry barrens' of Maine are mainly in Washington County and are about 150,000 acres in extent. There are, however, many thousand acres in other parts of the State that are or might be made profitable blueberry lands.
>
> "Blueberry lands that are treated systematically are usually burned over every third year for the purpose of renewing the bushes and of checking the growth of the alders, birches, etc. Lands bearing the high-bush blueberry are seldom burned over.
>
> "The station is now making an effort to introduce several species into cultivation. This is done by transfering some of the most productive and largest fruited plants to the garden, and by growing seedlings from selected fruit.
>
> "The few attempts that have been made at garden culture of the blueberry, indicate that with care satisfactory results may be obtained."

Strawberry notes for 1899, L. R. TAFT and H. P. GLADDEN (*Michigan Sta. Bul. 176, pp. 14*).—Data as to sex, vigor, blooming period, first and last ripe fruits, productiveness, size, form, color, quality, and firmness are tabulated for 160 varieties of strawberries grown at the station in 1899. Descriptive notes are given of 103 of these varieties.

> "The most promising of the new sorts are: Excelsior, Flash, Lady Franklin, Nick Ohmer, Ponderosa, Sample, See No. 3 and No. 4. Of the varieties that have been grown for 2 seasons, the following have made the best showing: Bryant, Fountain, Hoosier, Knight, Morgan Favorite, and Ridgeway. Bubach, Haverland, Lovett, and Warfield, with Beder Wood, Sharpless, or Clyde as fertilizers still have a place as money-making sorts. If fancy fruit under intensive culture is the object of the grower, he will find in Brandywine, Glen Mary, Marshall, and Wm. Belt sorts well worthy of his attention. Mayflower as an early berry and Michigan for late are worthy of trial for the purpose named."

The experimental vineyard—second report, W. B. ALWOOD (*Virginia Sta. Bul. 94, pp. 119–143, figs. 6*).—A revised edition of Bulletin 30 of the station (E. S. R., 5, p. 873). The establishment, planting, and training of young vineyards, especially for home use, are considered. The low-headed recurved fan system and the high-headed Y Kniffen system of pruning are described in detail, original illustrations being given of partly pruned vines at different stages of growth. Descriptive notes are given of 39 varieties of black grapes, 28 of red, and 44 of white grapes growing at the station.

The following varieties are recommended for general culture in Virginia:

"*Black grapes.*—For table and market: Concord, Moore, Early Market, Ives (not a good table grape unless well ripened). For wine: Clinton, Cynthiana, and Norton. Ozark has some promise as a late-market grape.

"*Red grapes.*—Brilliant and Delaware for table and market. Brighton for table. Ulster a fair table grape, late.

"*White grapes.*—Willie Bell, Niagara, Winchell, and Martha for both table and market. Elvira and Elpo for wine; also good for table. Lady and A 193 for table."

The same varieties are classified according to season as follows:

"*Very early:* Lady and Moore. *Early:* Early Market and Willie Bell. *Medium early:* Eumelan, Amber Queen, Geartner, and Brighton. *Medium:* Salem, Concord, Delaware, Niagara, Brilliant, Winchell, Olita, Ideal, Ives, Peter Wylie, A 193, Duchess, Cynthiana, and Norton. *Medium late:* Elvira, Martha, Elpo. *Late:* Ulster, Lady Washington, Ozark, and Clinton."

Chemical fertilizers on vines in 1899, E. SCHUARD and C. DUSSERRE (*Chron. Agr. Canton Vaud, 12 (1899), No. 24, pp. 519–521*).—Experiments were made to see if the enormous quantities of barnyard manure used in fertilizing vines could not be replaced in part by commercial fertilizers. Three plats were used in the test. One received the usual amount of barnyard manure; the second one half this amount and in addition sulphate of potash at the rate of 2,000 kg. per hectare and superphosphate at the rate of 500 kg. per hectare, or Thomas slag at the rate of 1,000 kg. per hectare, and the third the same fertilizers as the second, and in addition 400 kg. of nitrate of soda per hectare.

The plats receiving the mixed fertilizers gave increased yields over the plat receiving the barnyard manure alone. Plat 2, which received no nitrate of soda, yielded at the rate of 690 liters of wine per hectare, while plat 3, which received nitrate of soda, yielded at the rate of 775 liters of wine per hectare. The fear that the increase in yield would be accompanied by a decrease in the quality of wine proved to be unfounded, as the reverse was true and the wine obtained from plat 3 was of better quality than that obtained from either of the other plats.

Dependence of the fruit development of grapes and some other fruits on the development of the seed, H. MÜLLER-THURGAU (*Landw. Jahrb. Schweiz., 12 (1898), pp. 135–205, pls. 4; abs. in Centbl. Agr. Chem., 28 (1899), No. 12, pp. 828–839*).—The author reports the results of an extended study on the dropping of grapes; the origin of seedless grapes; seeds in normally developed grapes; influence of seed on the size, form, and color of grape berries; dependence of the ripening of fruit on the development of the seed, and on similar relations in other fruits.

Dropping of grapes.—It has been held that the early dropping of grapes was due to nonfertilization. The author shows that fertilization, in the ordinary meaning of that term, is not necessary for the development of grape berries, but that the growth of pollen in the pistil of the flower, even if no pollen tube penetrates the ovule, exercises such a stimulating influence that full-sized berries may develop and ripen, though no seed is formed. When no pollen growth in the stigma or ovary occurs, further development is prevented and the ovary soon withers and drops off. According to the author's investigations, the causes which prevent the growth of pollen in the stigma and ovary and thus occasion the dropping of the undeveloped berries are 3 in number: Outer deformities of the flower; inherited inner deformities, chiefly abnormal metabolism, and unfavorable environment.

Relative to outer deformities, the frequent occurrence among varieties of grapes, especially among American varieties of *Vitis riparia* having flowers with well-developed stamens and anthers, but with more or less stunted pistils, are noted. Further, it is noted that flowers may have well-developed pistils but degenerate anthers, so that fertilization can take place only through insect visits or by the aid of the wind. Such varieties are yearly subject to the dropping of the immature green fruit to a marked degree. Where these conditions prevail, the remedy is to immediately remove such vines from the vineyard. The ease with which the deformed flowers can be detected makes the application of this method of handling practicable.

In other instances, flowers may be seemingly perfect in their organs and yet fail to develop fruit. Many experiments were made with such vines, which were subject to the dropping of the fruit, by ringing them from 8 to 14 days before the blossoms opened, on the canes beyond the first shoots reserved for wood development. The ringed vines produced normal sized, though usually seedless, fruit, while the fruit on the vines not ringed nearly all dropped off soon after the blossoming period. Partial ringing of the vines, pinching off the tips of the shoots, or pruning away part of the flowers was of no benefit whatever. A practical consideration in this connection is to carefully avoid the use of scions for planting which originate from vines regularly subject to the dropping of their fruit, since these scions are certain to perpetuate the undesirable qualities of their parents. The author holds that the ringing of the vines does not cause a change in the structure of either stigma or ovary, but does, through better nourishment, occasion a change in the functional capabilities of these organs. A more abundant and more suitable secretion is formed on the stigma, and the chemical constituents of the cells of both stigma and ovary are, in a measure, changed.

The results of the author's experiments led to the conclusion that one of the real causes of the dropping of the grapes is an insufficient or unsuitable nourishment of the flowers with organic food. Ringing lessened the amount of water supplied, and concentrated the liquid nourishment carried to the flowers. In this connection the author examined comparatively ringed and unringed grape shoots for sugar. Examinations of such shoots made at the end of from 3 to 5 days showed practically no difference in sugar content. At the end of [illegible] days ringed shoots averaged 1.7 per cent sugar content and unringed shoots 1.4 per cent. At the end of 20 days ringed shoots averaged [illegible] per cent sugar content, and unringed 1 per cent. In cold, wet weather the sugar content of ringed and unringed shoots was reduced to 0.08 and 0.04 per cent, respectively. The author recommends ringing the canes bearing the shoots rather than ringing the individual shoots, as is frequently done, since it secures the same results and lessens the danger of the shoots breaking off. If the width of the ring is limited to 2 to 3 mm., the wound heals over after it has fulfilled its purpose, and the vines then develop normally.

The method of pruning was also found to influence the dropping of grapes. Certain varieties, as, for example, Gumpoldkuchen, must be pruned long in order to secure the least dropping of the fruit, while Elbling required short pruning.

As to the influence of environment on the dropping of fruit, excessive dry weather, long-continued cold, rainy weather, or a long period of low temperature alone have been found conducive to the dropping of the fruit. Short periods of rainfall, on the other hand, or a longer period of warm rainfall, did not seem to further the dropping. Low temperature is thought to exercise an unfavorable influence on the metabolism of the flowers; evaporation and the formation of sugar in the leaves are retarded, as is likewise the solution and utilization of organic reserve material.

Origin of seedless grapes.—Seedless grapes occur whenever the growth of pollen takes place in the stigma and ovary, but, when for any reason, impregnation of the ovule fails to take place. These grapes ripen earlier than normally developed grapes and are much smaller in size. The cell walls are thinner and they are in general much less compactly formed. The author gives comparative measurements of the grape pedicel and of the epidermis, bast layer, wood, pith, etc., of the same. The measurements show the average diameter of the pedicel of normally developed grapes and of the other parts mentioned to be nearly 3 times greater than that of seedless grapes. Considerable data is given relative to the comparative weights of normal and seedless grapes and of the sugar and acid content of the same at different dates of gathering. The data show that the process of ripening takes place much earlier in the seedless grape. At vintage time these grapes are overripe; they are usually commencing to wrinkle, and are subject to the harmful working of wasps, bees, and fungi.

The author's investigations led him to arrange the causes which conduce to production of seedless grapes under 3 heads: (1) The pollen tube may extend into the ovary, but fail to penetrate the ovule. The fruit in this case develops, but is small and no seeds are formed.

The varieties Aspirant, Pearl, Grobriesling, and the Corinthian raisins of commerce belong to this group. (2) The pollen tube may penetrate the ovule, but the ovule be incapable of fertilization. The seeds in this case show a somewhat greater development than in the first case and the berries are a little larger. The varieties Corinth and Sultana belong to this group. (3) The ovules may be capable of fertilization, but the pollen defective. If the pollen fails to germinate, no fruit whatever develops and the blossoms soon drop off. Such grapes may be fertile when supplied with effective pollen. The varieties White Damascus, Madeline Agevine, and "Olivette Noire" often contain specimen vines which come under this head.

Number of seeds in normal grapes.—A normal grape ovary contains four ovules. These seldom all develop. The author examined 100 ripe berries of each of 22 varieties. A few of the same varieties were also examined in different years, and in one experiment the number of seeds in grapes protected from foreign pollen and outer influences by sacks placed over the bunches before blossoming was determined. These data are tabulated. Berries containing 1 or 2 seeds were found most abundant. Then came seedless berries, followed by three-seeded and four-seeded berries. Nonprotected berries contained but few more seeds in 100 berries than berries protected before and during the blossoming period with sacks. Newly cultivated sorts, as certain American varieties, usually contain a larger number of seeds than older European varieties.

The weather seems to exercise an influence on the number of seeds which develop. The average number of seeds in 100 berries of 4 varieties in 1888 was 160; in 1889, 225; and 1890, 142. Planting different varieties together had no apparent influence on the number of seeds in the berries.

Influence of the seed on the size, form, and color of grapes.—The data given on this subject show that the size of the grape berry increases regularly with the number of seeds it contains. The average weight of the flesh of seedless grapes taken from a large number of varieties was 42.7 gms. The average weight of the flesh of one-seeded grapes was 144.5 gms.; of two-seeded grapes, 204.2 gms.; of three-seeded grapes, 253.6 gms.; and of four-seeded grapes still greater. The data also show that the better the seed development the larger the size of the berry. One well-developed seed exercises a greater influence on the flesh development of the berry than two poorly developed seeds.

The form of the berries is influenced by the seed. Seedless berries are practically round, while berries containing seeds are more oblong. No relation between the color of the fruit and the number of seeds contained in the berry could be discerned.

Dependence of ripening on the development of the seed.—Extended examinations with reference to the sugar and acid content of different varieties of grapes gathered at different dates and containing no seed, and 1, 2, or 3 seeds, led the author to the following conclusions: (1)

The sugar content is highest in the seedless grapes, and these grapes are also ripest. One-seeded grapes stand next in percentage of sugar, followed by the two-seeded and three-seeded grapes. (2) The acid content is least in the seedless berries and greatest in the three and four-seeded berries. (3) Both the sugar and acid content increased absolutely with the increase in the number of seeds in the berry, and the acid content increased more rapidly than the sugar content.

Berries which contained only 1 or 2 seeds began ripening first on the side containing no seed. A microscopical examination of the pedicels of one-seeded berries showed that the different stages of ripeness of the 2 halves of the berries could be seen in the corresponding halves of the pedicel. The half of the pedicel on the seedless side was not only weaker in development but also poorer in starch content, signifying that berries when ripening draw on the reserve starch content of the pedicel. Unfavorable conditions, as cold or the development of seed in the berry, which stimulates and therefore prolongs the period of growth of the flesh, retard the ripening process. The more seeds in the berry the greater the stimulation and therefore the longer the period of growth, the greater the size of the berry, and the later the period of ripening.

The use of cuttings from vines which are subject to the production of seedless berries should be avoided. The aim should be to select vines for planting which produce grapes having a uniform number of seeds in the berry. The product will then be uniform in size and ripen at the same time.

Relation to other fruits.—Investigations similar in character to those conducted with grapes were made by the author with certain orchard and bush fruits which show that the general principles involved in the seed production, fruitfulness, growth of flesh, and ripening of the fruit of grapes have a general application to other fruits. An outline of the author's work along this line is here reported, but the greater part of the details are reserved for a future report. With both apples and pears, fertilization of the ovaries is not necessary to the production of fruit. The penetration of the pollen tube into the ovary exercises sufficient stimulation to cause a production of fruit. Seedless apples and pears are not found as often as seedless grapes, but they do occur. With currants the largest berries were generally found to contain the greatest number of seeds. When 2 berries were of equal size, the berry containing the least number of seeds ripened first. The author was unable to determine whether seedless apples and pears ripened before those containing seed.

In the case of apricots and nectarines only one of the two ovules present develops into a seed, the other remaining an empty sack. The half containing the developed seed is not only more completely rounded out, but the flesh is much firmer. This development gives to these fruits their peculiar unsymmetrical form.

Manual of practical viticulture, M. E. Durand (*Manuel de viticulture pratique. Paris: J. B. Baillière & Sons, 1900, pp. 400, figs. 146*).

Culture of asparagus (*Semaine Agr., 20 (1900), No. 973, p. 5*).—Methods followed in the vicinity of Paris.

Culture of peas and the manufacture of pea products, A. DE CÉRIS (*Jour. Agr. Prat., 1900, I, No. 4, pp. 133–138, figs. 2*).—The culture of peas for canning is considered and a description given of factory machinery and pea canning operations. The use of the pods as a green and preserved fodder is considered.

Winter budding, H. M. STRINGFELLOW (*Nat. Nurseryman, 8 (1900), No. 1, p. 5*).—Detailed directions for winter budding are given.

Pomology in Rhode Island, L. W. RUSSELL (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 29–49*).—Lists of orchard and small fruits most successfully cultivated by growers throughout Rhode Island, with comments by the different growers; and suggestions for locating and managing orchards with reference to Rhode Island conditions.

Propagation of Drosera binata (*Amer. Gard., 21 (1900), No. 269, p. 117, fig. 1*).—This plant has been successfully grown by placing the leaves, cut into small sections one-half an inch or more in length, on sphagnum and sand. Several plants grow from each section.

Propagating violets, E. J. (*Gard. Illus., 21 (1900), No. 1089, p. 627*).—Propagation by runners is especially considered.

Effect of electric light on Easter lilies, M. G. KAINS (*Florists' Exchange, 12 (1900), No. 6, p. 131*).—From his preliminary work the author says "the light might be used to advantage after the buds are an inch long in order to make them expand sooner than they naturally would."

Horticulture in Holland, J. K. L. M. FARQUHAR (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 203–212*).—Lecture on flower and bulb culture in Holland, delivered by the author before the Rhode Island Horticultural Society.

The beech and its varieties (*Garden, 57 (1900), No. 1471, pp. 64, 65, fig. 1*).—Different varieties of cultivated ornamental beeches are described.

A new evergreen (*Nat. Nurseryman, 8 (1900), No. 1, p. 4, fig. 1*).—A description, accompanied by an illustration, is given of a hybrid evergreen tree originated by crossing Golden Arborvitæ with *Rentinospora squarrosa*. The tree is a dwarf and grows but 6 or 8 ft. high.

FORESTRY—SEEDS.

Practical forestry in the Adirondacks, H. S. GRAVES (*U. S. Dept. Agr., Division of Forestry Bul. 26, pp. 85, pls. 20*).—This bulletin states the general conditions which govern forest management in the Adirondacks, and gives a report of the work already done and results accomplished in that region under the cooperative plan previously described (E. S. R., 10, p. 443).

The forestry problem of the Adirondacks is discussed in detail, with special reference to 2 private preserves amounting to about 100,000 acres which are under special consideration. A description is given of these tracts and of the forests growing on them, and a special study of the habits, growth, and production of spruce, with mention of associated species. In connection with the special working plan, the loss occasioned by ordinary lumbering is discussed in detail, to show the advantage of conservative methods.

The author discusses an American system of forestry, as opposed to that usually known as the European system. The latter system contemplates the maintenance of a sustained annual yield, the removal of dead and unsound trees, thinnings and improvement cuttings, permanent roads, planting, and fire lines. While this system may be adapted to European conditions, it fails in application in this country for many reasons. The system of management advocated contemplates the removal of the spruce, that being the principal market material, above 10 in. in diameter at 3 ft. from the ground, except seed trees needed to restock the opening made in lumbering. By observing this plan of cutting, it is believed that the original cut may be obtained again in from 30 to 36 years. The owners of the preserves are satisfied with the income thus obtained, and satisfactory contracts with lumbermen can be made.

In a number of respects the first year's work proved unsatisfactory, but it is confidently asserted that the second year's lumbering is beginning under better conditions and with the promise of great improvement in the character of the work.

The form of agreement under which this work is being conducted, rules for cutting, and volume and yield tables are given, the latter being quoted from "The Adirondack Spruce" by Gifford Pinchot.

Natural reproduction of forests in old fields in eastern Kentucky, S. C. MASON (*Forester, 5 (1899), No. 11, pp. 251–255*).—After reviewing the geological conditions of the area covered by this report, the author gives an account of the natural reforestation of a number of old fields. The original timber over this region consisted of oaks, sweet gum, cherry, sassafras, maple, chestnut, hickory, and large numbers of Jersey scrub pine, with occasional specimens of yellow pine. Most of this had been cut off and the fields cultivated for some time, after which they were abandoned.

In the first field, upon which cultivation ceased about 15 years before the observations, there was a complete stand of young pines, mostly *Pinus virginiana*, with about 10 per cent of yellow pine. There were a few oaks and hickories, but their number was insignificant.

In the second field, which had been abandoned for about 40 years, there was a complete stand of pine, though some trees had been cut. The stand was about one tree to every 8 sq. ft. On an average the specimens of *P. virginiana* were found to be 9½ in. in diameter 2 ft. from the ground, showing 38 growth rings on the stump. A small mixture of yellow pine was observed, but from the testimony of the owner and from evidence presented, it seems that the black pine overtops the yellow to the serious injury of the latter. One specimen of yellow pine was 8.5 in. in diameter and 59.5 ft. high, and showed 37 growth rings at 2 feet.

The third field was partially situated in a hollow, and has practically the same history as the second. Instead of a full stand of trees, they are arranged in groups and are heavier, shorter, and broader topped, except in the center. The yellow pines under such conditions form a clear trunk for a considerable distance, the young trees seeming to do this under their own cover. On the sides of the hollow the stand is fuller, both species of pine being about equally represented. Many trees were observed which were 10 and 12 in. in diameter, and again the yellow pine presented straighter and cleaner trunks.

The fourth field was located on a rather thin gravelly soil on top of a limestone bluff, and had been abandoned for about 20 years. The growth was wholly of black pine and was exceedingly dense, the average height of the trees being about 20 ft., with a diameter of 3 in.

The fifth field reported upon had been in cultivation for a long time, and at one time contained an orchard, but had been abandoned for about 40 years. Upon this the predominating growth was hard wood, though some pines were present. The growth was very dense and the young trees reached up to 50 or 70 feet, with clean, straight trunks clear of branches from 20 to 40 feet. The cover was almost perfect. The species most numerous were black and falcate oaks, some of which were a foot in diameter. White oaks were next in number, followed by black oak, hickory, and at the lower end of the field a number of poplars (*Liriodendron tulipifera*).

The sixth field was cultivated for a number of years, but the last crop raised upon it was in 1864. It is now entirely covered with a full growth of thrifty timber, more than half of which is poplar or whitewood.

Specimens of this tree a foot from the ground were 17 in. in diameter and showed 33 growth rings, which would indicate that the age of the tree was about 34 or 35 years. Two species of hickory were present in considerable quantity, and a large number of black locusts had been cut from the tract for posts.

On the influence of different degrees of thinning on the growth of beech, A. C. FORBES (*Trans. Roy. Scot. Arbor. Soc., 16 (1899), pt. 1, pp. 116–122*).—The author reviews the statements made by Schwappach relative to the growth of beech woods in Germany and comments upon the different methods adopted for thinning. The general conclusions of Schwappach are concurred in, and the author believes that the best results can be obtained by at first confining attention to the removal of rubbish, beyond which little is required until the thirtieth year on good, or forty-fifth year on bad, soils, and at that time the main-crop thinning should begin. About every six years the woods should be gone through and all badly shaped trees taken out, groups of well-shaped trees isolated, and all dead and dying ones removed. When this has been done 6 or 7 times, the crowns of the best trees should meet at about their seventieth or eightieth year. After this, stronger thinnings, bordering on light fellings, may be begun and recur every 8 or 10 years, removing the poorest and leaving the best trees. In this way about 1,000 ft. of timber per acre should be obtained every 10 years.

Root suckers on Douglas fir, F. H. LAMB (*Bot. Gaz., 28 (1899), No. 1, pp. 69, 70*).—The occurrence of stool shoots among deciduous trees is said to be very common, but among conifers, so far as present information goes, they are confined to California redwood, California nutmeg tree (*Tumion californica*), and the short-leaved or yellow pine (*Pinus echinata*). The author reports having observed similar outgrowths from the Douglas fir in the forests of western Washington. These growths, which are commonly called sap suckers, range in height from 0.6 to 3.5 meters, are without leaves or branches, and appear entirely lifeless until cut. Examination shows that they are covered with a living bark, and beneath that a living woody tissue which possesses a very fine-grained, intricate burl. These sap suckers are only a secondary growth from ordinary root suckers, and are found only in the most moist and dense forests, and even under those conditions are reported as being very rare.

What forestry means to the United States, J. WILSON (*Forester, 5 (1899), No. 12, pp. 271–275*).—A paper by the Secretary of Agriculture, in which attention is called to the value of forests and the necessity of their conservation and management.

The effect of forests on water supply, H. HAWGOOD (*Forester, 5 (1899), Nos. 11, pp. 247–251; 12, pp. 279–281*).—A résumé is given of the present information relating to the effects of forests on the conservation of water supply.

The State and forestry, W. S. MELICK (*Forester, 5 (1899), No. 8, pp. 178–181*).—The author suggests that there should be a formulation of systems of protection and propagation in forestry, after which an attempt should be made to introduce the system by the education of the people and by proper legislation.

The forest problem in the West, A. KINNEY (*Forester, 5 (1899), No. 9, pp. 200–203*).—A paper read before a meeting of the National Forestry Association, in which the peculiar forest conditions of the West and Southwest are stated.

The practical in forestry, W. W. EVERETT (*Forester, 5 (1899), No. 12, pp. 275–278*).—This paper treats, from the lumbermen's standpoint, the various ideas concerning lumbering, forest conservation, and reforestation.

Second-growth pine vs. agriculture, E. BRUNCKEN (*Forester, 5 (1899), No. 11, pp. 255, 256*).—The author reviews the condition of cut-over pine lands in Wisconsin and Minnesota, and draws the inference that while some kind of agriculture can be carried on over a considerable portion of these tracts, the interest of the settlers and people themselves is rather in the line of forest preservation and management.

The restoration of denuded forest areas by pasturage, J. A. GUNDY (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 588–596*).—The author maintains that pasturing cut-over lands after the young seedlings have obtained a height when their crowns can not be reached by stock, will prove not only beneficial to forests by keeping down forest fires, but sufficiently remunerative to make the fencing of denuded areas profitable.

Pure forests and mixed forests, D. BRANDIS (*Trans. Roy. Scottish Arbor. Soc., 16 (1899), pt. 1, pp. 13–24*).—The advantages and disadvantages of pure and mixed forests are pointed out, the advantages of pure forests being that their management is simple and easy, while the disadvantages are the greater liability to damage by wind and sun, insects, and fungus diseases. The author describes a number of pure and mixed forests, and proposes a method whereby the oak and Scotch pine forests may be converted into mixed woods.

The growth of reserve trees after lumbering, E. HENRY (*Bul. Soc. Sci. Nancy, 2. ser., 16 (1898), No. 33, pp. 1–14*).

Forest thinnings, BROILLIARD (*Trans. Roy. Scottish Arbor. Soc., 16 (1899), pt. 1, pp. 100–115*).—The author discusses the necessity of forest thinnings and the problem in relation to the requirements of a number of different species of trees. The general statement is made that no definite formula for thinning can be laid down, as there is no process or equation by which one can determine the number of trees to remove or which ones are to be cut. This must be done through a knowledge of the various species, their requirements, exigencies, mutual relations, etc.

Height growth in forestry plantations, J. SIMPSON (*Gard. Chron., 3. ser., 26 (1899), No. 662, pp. 187, 188*).—The influence of location of plantations on growth in height is pointed out and numerous instances of growth cited.

A plan for the management of the woods of the Novar Estate for twenty-five years, F. BAILEY ET AL (*Trans. Roy. Scottish Arbor. Soc., 16 (1899), pt. 1, pp. 25–95*).—Working plans are given for forests embracing nearly 4,000 acres, the principal stock of woods being Scotch fir, larch, spruce, Douglas fir, and various hardwoods. The past management of the forest is reviewed and the plan outlined for the future.

Notes on the Raith and Novar working plans, R. C. M. FERGUSON (*Trans. Roy. Scottish Arbor. Soc., 16 (1899), pt. 1, pp. 96–99*).—The author comments upon the working plans that have been adopted for these estates.

A forestry experimental station, A. C. JOHNSON (*Forester, 5 (1899), No. 8, pp. (185–187)*).—An account is given of the forestry station at Santa Monica, Cal. At this place a large number of trees have been tested in a more or less satisfactory manner. It has been found that *Eucalyptus globulus* and *E. robusta*, although succeeding well in some regions, are not adapted to the Foothills Region. Several varieties have been found suited to this purpose and it is thought that probably others can be found. The advantage of such experiments, properly conducted, is pointed out, and better support is urged for similar institutions.

Supplementary report of the commissioner of forestry, J. T. ROTHROCK (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 444–465*).—A review is given of the forestry conditions of the State and the losses occasioned by forest fires. For the year covered by this report it is stated that the loss due to forest fires would be reduced at least

40 per cent over the loss of the previous year. A brief review is given of forestry in other States, and the subject of tree pruning as related to forest conditions is discussed at considerable length.

Catalogue of the trees and shrubs in the arboretum and botanic garden at the Central Experimental Farm, W. Saunders and W. T. Macoun (*Canada Cent. Expt. Farm Bul. 2, 2. ser., pp. 88*).—A catalogue of the trees and shrubs grown under the auspices of the Central Experimental Farm is given in the hope that it may assist in the correct naming of varieties and be the means of bringing such useful and hardy species as are deserving of more general cultivation into greater prominence.

Forest trees and shrubs, P. Mouillefert (*Traité des arbres et arbrisseaux forestiers. Paris: Paul Klincksieck, 1898, pp. VIII+1403, pls. 195; rev. in Bul. Soc. Bot. France, 46 (1899), No. 1-2, pp. 60, 61*)—The author has described 2,450 kinds of trees and shrubs occurring in the forests of Europe, and especially in France. They include the useful and ornamental, whether cultivated or not.

The species and varieties are described in greater or lesser detail, and the country where they originated and their natural habitat given. Methods of culture, utilization, structure of wood, products of the trees, etc., are described.

The ash (Fraxinus excelsior), and its cultivation, J. Nisbet (*Trans. Roy. Scottish Arbor. Soc., 16 (1899), pt. 1, pp. 128-131*).—The value of this tree for its timber and as a forest tree is pointed out, and its leading characteristics as a tree are stated. It is said to demand considerable light and air and to make heavy requirements on the moisture and mineral matter of the soil. This tree has been chiefly grown in Great Britain as a hedge row tree, and if grown upon purely economical principles the proper position of the ash is that of a subordinate tree in woods consisting of other trees of somewhat slower growth. As a standard tree in copse the ash finds conditions well suited to its requirements, and here it attains its best development and highest market value.

Notes on the larch woods of Scotland, E. Nilson (*Trans. Roy. Scottish Arbor. Soc., 16 (1899), pt. 1, pp. 123-127*).—Comments are given on the condition of the larch woods of Scotland as observed by the author in a visit made to study the larch with special reference to Swedish conditions.

Mechanical tests of Ceylon timber, W. C. Unwin (*Indian Forester, 25 (1899), No. 10, pp. 411-415*).

Seed testing, C. D. Woods (*Maine Sta. Rpt. 1898, pp. 60-63*).—Tabulated results are given of the examination with regard to purity of 45 samples of red clover seed, 1 of white clover, 24 of alsike clover, 1 of peavine clover, 51 of timothy, 7 of redtop, 1 of orchard grass, 1 of Kentucky blue grass, and 3 of Hungarian grass. Seeds of 33 species of weeds were found in the 134 samples.

DISEASES OF PLANTS.

Cereal rusts of the United States, M. A. Carleton (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 16, pp. 74, pls. 1, fig. 1*).—This bulletin contains in part the results of investigations by the author on the diseases of cereals. These studies have been carried on in the laboratory and field for a number of years, and include investigations into the life history of the fungi, in which some important facts relative to the breeding of rust-resisting varieties of cereals were obtained.

The several species of rusts affecting cereals in the United States are fully described and the distribution given, together with detailed statements of the results of observations and experiments to determine the rust resistance of numerous varieties of wheat and oats. Many inoculation, germination, and physiological experiments showed that, in addition to the commoner forms described, the cereal rusts have distinct specialized forms on various grasses. As none of these forms occur on cereals, they are of little economic importance.

From the author's conclusion it appears that at least 6, and possibly 7, distinct rusts affect the cereals of the United States, as follows: Orange leaf rust of wheat (*Puccinia rubigo-vera tritici*), orange leaf rust of rye (*P. secalis*), crown rust of oats (*P. coronata*), black stem rust of wheat and barley (*P. graminis tritici*), black stem rust of rye (*P. graminis secalis*), black stem rust of oats (*P. graminis avenæ*), and maize rust (*P. sorghi*). Of these the black stem rusts of wheat and oats are by far the most destructive, that occurring on maize being of slight importance.

The leaf rusts are evenly distributed over the United States wherever their hosts are grown. The stem rusts are most prevalent between the Allegheny Mountains and the ninety-fifth degree of west longitude north of the thirty-seventh degree of north latitude, and in portions of Texas and California. The leaf rusts and crown rusts are proportionately more important in the Atlantic and Southern Coast States.

The author believes that the damage to wheat and oats from rusts probably exceeds that caused by any other fungus or insect pest, and in some localities is greater than that due to all other enemies combined.

Concerning rust resistance of cereals, the author states that there is as yet little certainty, as little attention has been paid to testing varieties in this respect. A number of more or less resistant varieties of wheat and oats are mentioned, some of which seem to secure their immunity by their early ripening. The Durum and Poulard wheats are very resistant to the leaf rust, but are comparatively little grown in this country.

Experiments with uredospores show that the orange leaf rusts of wheat and rye do not transfer to hosts outside of the genera Triticum and Secale. On the other hand, the uredo stages winter over readily in this country, beginning first on selfsown grain and probably later transferring to the regular fall-sown crop. On this account volunteer wheat and rye should be rigidly excluded.

The crown rust of oats is not yet known to winter in its uredo form or to transfer to other hosts than to species of Avena. Later experiments, however, show that the æcidium of *Rhamnus lanceolata* infests oats, *Phalaris caroliniana* and *Arrhenatherum elatius*. The black stem rust of wheat is known to occur also on barley and *Hordeum jubatum*. So far it is not known to winter in the uredo stage. While it is not definitely determined, the author thinks that there is a distinct form of the black stem rusts occurring on rye in this country. The uredo of the black stem rust of oats is not known to winter in the United States, but it has been found alive very late in the autumn. The rust is very common on orchard grass and *Arrhenatherum elatius*, hence oats may be easily infected when grown in close proximity to these grasses, The maize rust occurs also on teosinte in this country, but does not winter its uredo.

An extensive bibliography concludes the bulletin.

Treatment of seed oats to prevent smut, J. A. TILLINGHAST (*Rhode Island Sta. Rpt. 1898, pp. 192–203*).—In continuation of his investigations the author treated 13 varieties of oats with the Jensen hot-water treatment as a smut preventive and also with Ceres Pulver to compare their relative efficiency in preventing oat smut. The different lots of oats were carefully weighed so as to secure equal amounts in each case. Those for the Jensen treatment were immersed in water at a temperature of 115° F. until thoroughly wet and warm, then in water at 132.5° for 10 minutes, after which they were thinly spread to dry. For the Ceres Pulver treatment the oats were put in small heaps, and the powder dissolved as per directions and sprinkled over them, turning and mixing them thoroughly so that each seed might become wet with the liquid, after which they were thinly spread to dry.

The oats were all sown April 28 and showed no decided difference in germination or growth except a tendency on the part of the treated seed to produce slightly taller plants. The yield of the different plats is tabulated, from which it appears that as a whole the Jensen treatment proved thoroughly efficient in preventing smut and also tended to increase the yield of both grain and straw. The Ceres Pulver treatment, while not entirely effective in destroying the smut spores, increased the average yield of grain and straw, and quite largely reduced the percentage of smut in most cases. The average gain due to treatment of all varieties was 17.81 per cent of grain and 12.75 per cent straw.

Notes are given on the growth and yield of the different varieties of oats used in the above trial and also their liability to rust and tendency to lodge.

Wilt disease of cotton, watermelon, and cowpea, E. F. SMITH (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 17, pp. 72, pls. 10*).—The cause of the peculiar wilt of these plants has been under investigation for a number of years and has been referred by the author and others to a number of fungi. In the present bulletin the cause is attributed to a new genus of fungi to which the name Neocosmospora has been given, the species being *N. vasinfecta*, occurring on cotton and probably on okra, *N. vasinfecta tracheiphila* on cowpeas, and *N. vasinfecta nivea* parasitic on the watermelon.

While the parasitism of the fungus on cotton and cowpeas is not proved, the evidence seems to indicate that the fungus lives parasitically on these hosts. The biology of the fungus is described at considerable length. Its behavior on a large number of media is described as well as the different forms occurring in its life cycle. The host plants, as already indicated, are cotton, watermelons, cowpeas, and probably also okra. The fungus lives from year to year in the soil and is peculiarly a soil organism, always attacking the plant from the earth. The internal conidia occur in the vessels of the living plant throughout the season, and cause the disease known as blight or wilt. The external conidia are observed whenever plants have been killed by the internal fungus. The perithecia occur from August to November.

The geographical distribution of the fungus is sketched, showing that it is widely spread in the Southern States, and may be looked for from Texas to New Jersey. Except in one place in Arkansas, so far as known, it occurs only in the Atlantic and Gulf States.

The parasitism of the fungus and numerous infection experiments are described, from which it appears that successful infections of watermelons were abundant. On the cotton plant all inoculations have failed. Cross inoculations on the melon with the cotton fungus have been successful, as were cowpea inoculations on both melons and cotton. Attempts to inoculate a number of other plants were unsuccessful.

The gross symptoms in the watermelon are those shown in a rapidly transpiring plant supplied with insufficient moisture, resulting in the sudden wilting of the plant. The uniformity with which the fungus seeks out the vessels of the plant is very striking, and the water ducts are clogged to such an extent that they can not perform their necessary functions. The leaves of the cowpea usually become unjointed and fall off, leaving the green stems bare. In some cases they become yellow and fall off without showing any previous trace of the disease. In the case of the watermelon, the leaves do not become yellow when they fall off, but suddenly wilt and shrivel so that a large vine may lose all its foliage in from 24 to 48 hours. The cotton plant appears less susceptible and, as a rule, contains less of the fungus, often recovering partially so as to produce some fruit. The xylem of the deceased plant becomes brown, and in case of the translucent stem of the cowpea this stain shows through the green bark, giving an unusually dark appearance to the living stem.

While no cure is known for the disease in the case of the watermelon, which seems to be most attacked, it is recommended that fields already infested should not be planted with melons for a long series of years, but other crops grown in their stead. Infection can readily take place through the wash of lands already contaminated, as well as by dirt adhering to implements and to the feet of horses, cattle, etc. The vitality of the fungus is very great, and wilting melon vines should be collected and burned. Care must be taken not to introduce the fungus into the barnyard, and where there is reason to suspect the manure pile, commercial fertilizers should be used instead. A number of important steps in the life history of the fungus remain to be studied, but on account of the importance of the work, it is considered advisable to publish the information now at hand.

Treatment for gooseberry mildew, C. P. Close (*New York State Sta. Bul. 161, pp. 153–164, pls. 2, dgm. 1*).—In view of the destructive character of gooseberry mildew and its economic importance, experiments have been undertaken for treating the disease on a commercial scale. These investigations were begun in 1897 and were continued for three seasons. Two commercial plantations have been under experiment, and a preliminary report giving the result of the work in 1897 was given in Bulletin 133 (E. S. R., 9, p. 1061).

The fungicides used were Bordeaux mixture, lysol, and formalin, comparisons being made with potassium sulphid. The result of spraying, as shown by the percentage of mildewed fruit for three seasons, is tabulated, from which it appears that spraying the gooseberry bushes with a solution of potassium sulphid, 1 oz. to 2 gal. of water, at a cost of about three-tenths of 1 cent per bush for 7 applications, gave the best results.

On a second plantation experiments were tried on the relative value of winter and summer treatments. In the winter treatments copper sulphate, potassium sulphid, iron sulphate, copper carbonate, and soda-Bordeaux mixture were employed. The results obtained in one year's experiment indicate that there is no gain derived from winter treatment. The soda-Bordeaux and copper carbonate solutions gave slightly better results than potassium sulphid, but not great enough to be of any significance.

The recommendation given in Bulletin 133, viz, that spraying with potassium sulphid, 1 oz. to 2 or 3 gal. of water, is repeated. The spraying should be begun as soon as the buds are breaking and continued at intervals of about 10 days.

Chlorosis in fruit trees, R. L. CASTLE (*Gard. Chron.*, *3. ser.*, *25* (*1899*), *No. 652*, *p. 405; 26* (*1899*), *No. 653*, *p. 1*).—An account is given of experiments conducted in an orchard to prevent the chloritic condition of the various kinds of fruits. The soil of the orchard was a heavy marl, the proportion of chalk being large. The land was fertile and remarkably well suited to such crops as peas, beans, clover, cabbage, turnips, etc. The behavior of the fruit trees was remarkable. In 2 years from planting the foliage would nearly always become pale or whitish, the following year the branches would become weaker, and in the case of cherry and apricot, the affected portions quickly died. In most cases fruit buds were not produced, but when any fruits were borne by apple and pear trees they failed to develop satisfactorily.

Experiments were conducted to ascertain the effect of chemical fertilizers on this disease. The chief substances used were sodium nitrate; potassium nitrate, sulphate, and chlorid; kainit, ammonium sulphate, ground bone; and various grades of superphosphates. A mixture of potassium nitrate, superphosphate, and iron sulphate produced marked and highly satisfactory results. Apricots recovered, pears and apples became healthy, and fruit was developed and well ripened.

Further experiments are to be conducted to ascertain the best form of superphosphates to be used.

An outbreak of chrysanthemum rust, B. D. HALSTED (*New Jersey Stas. Circ.*, *Nov. 15*, *1899*).—The author reports the receipt of many complaints concerning a destructive disease of chrysanthemums which is due to a species of rust, probably *Puccinia hieracii.* When badly infested the chrysanthemum plant becomes dwarfed, the leaves small and brown on the under side. Later on, instead of the green color of healthy plants, there are small, stiff, leafless stems, ending in stunted heads that fail to open into marketable flowers.

This rust has been known in this country for but a few years, and experiments with remedial measures are quite limited. It is considered of prime importance that the stock used for propagation should be free from disease, and in all stages of growth, from the beginning, they should be sprayed weekly with Bordeaux mixture or other equally effective fungicides.

New diseases of the violet, P. H. DORSETT (*Amer. Florist, 15 (1899), No. 591, pp. 246–248, figs. 5*).—The author reports a rather serious trouble with violets due to nematodes. The leaves of the plant become yellowish and sickly looking, hard and brittle to the touch, and break with a pronounced cracking sound when bent between the fingers. In every instance the crown bud is wanting, and numerous runners and wiry shoots are put out, which show the plant's efforts to overcome the trouble, but the new growth is dwarfed and distorted. The plants have good roots, are free from root nematodes, and practically free from fungus diseases. Examination of the buds showed that the worms appear to live wholly in the buds and young growing parts of the plant. To prevent the introduction and spread of the pest, all stock should be carefully inspected before planting, and should the trouble appear all affected plants should be removed and burned, and, if possible, the soil in the beds removed to a depth of 6 or 8 inches.

A second disease described is that due to a wood fungus, *Merulius lacrymans.* This fungus is common on wood, producing dry rot, and is almost invariably found close to or in some portions of the woodwork in the beds in which the plants are grown. It was found that the fungus spreads from the wood in the beds to the adjacent plants by means of rather coarse, white mycelium, and, reaching the base of a plant, develops a rather thick, fleshy hymenium. At first this is snow white, but later becomes yellowish or grayish. The parts of the plant which are attacked rot and decay and the plant is killed before the fungus reaches maturity.

Strong Bordeaux mixture seems to have had little or no effect in checking the fungus, and it is cited that a healthy growth took place all over the surface of a cypress shingle that had been thoroughly saturated with a strong solution of copper sulphate. As the cause of this disease is a wood fungus, the construction of benches of brick or concrete would obviate the difficulty.

Hot water as a cure for mildew and as an insecticide, G. B. MALLETT (*Gard. Chron., 3. ser , 26 (1899), No. 661, pp. 166, 167*).—Numerous comments have been made on the value of hot water as a fungicide and insecticide. In the present article the author gives his experience in combating insects and fungi with this means. It is stated that grape mildew has been totally destroyed on vines by spraying them with water heated to 180° F. The leaves and berries were quite free from injury. He has also tested water heated to 160° upon roses for the prevention of rose mildew, with favorable results. A table is given of temperatures to which water should be heated when used as an insecticide against a number of the more common insect enemies. The temperatures range from 130 to 145° and are said to be safely used on a number of plants, such as apples, peaches, chrysanthemums, roses, tomatoes, asparagus, cabbage, etc.

A compilation of the animal and plant parasites of tropical plants, A. ZIMMERMANN (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), Nos. 15, pp. 550–555; 16–17, pp. 582–597*).—Lists are given of 122 animal and 50 plant parasites. An extensive bibliography is also given.

Plant diseases in Italy during 1898, SOLLA (*Ztschr. Pflanzenkrank., 9 (1899), No. 5, pp. 297–299*).—Brief notes are given on the more important plant diseases observed at the laboratory of Pavia during 1898.

The influence of parasites of beet seed on the growth of sugar beets, J. STOKLASA (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 21, pp. 720–726*).—The investigations of the author show that parasitic animals and fungi on the seed balls of beets are often enabled to greatly weaken the plants or to destroy them entirely. On this account sugar beet seed should be treated with fungicides before planting and the early growth of the plantlets stimulated by the use of proper fertilizers.

Earcockle (Tylenchus scandens) (*Jour. Agr. and Ind., South Australia, 3 (1899), No. 5, pp. 431, 432, figs. 4*).—A brief account of the injury caused by this nematode in the heads of wheat. It is recommended that affected plants be pulled and destroyed.

A bacterial disease of beans, G. DELACROIX (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 17, pp. 656–659*).—The author describes a bacterial disease of beans which in certain regions near Paris has proved to be of considerable importance. Microscopic examinations have shown the presence of large numbers of bacteria, the characters of which are given. The author states that the disease does not differ essentially from that recently described by E. F. Smith, of this Department (E. S. R., 9, p. 1058), and the probabilities are that the diseases are identical.

From the nature of the disease, it is stated that preventive treatment is not possible, and that attention must be given to the choice of seed and rotation of crops.

Two sclerotia diseases of potatoes, E. J. MCWEENEY (*Trans. British Mycol. Soc., 1897–98, p. 67*).

Yellow blight of the potato, T. JOHNSON (*Gard. Chron., 3. ser., 26 (1899), Nos. 676, p. 440; 677, p. 477*).—An account is given of investigations made by the author in the west of Ireland on the cause of this disease. Two fungi, *Sclerotinia sclerotiorum* and *Rhizoctonia solani*, were found present. The tubers and stems are affected, and the presence of the sclerotia of the Rhizoctonia in the tubers gives rise to the disease known as smallpox of potatoes.

Tea blights (*Gard. Chron., 3. ser., 26 (1899), No. 673, p. 379*).—Attention is called to two serious diseases of tea in Ceylon, namely, gray blight, due to *Pestalozzia gulpini*, and brown blight, caused by *Colletotrichum camelliæ*.

Contributions to the knowledge of Melampsorella caryophyllacearum, P. MAGNUS (*Ber. Deut. Bot. Gesell., 17 (1899), No. 9, pp. 337–343, pl. 1*).—Notes are given upon this fungus, and its relationship with other forms is discussed.

Septoria graminum, parasitic on leaves of wheat, L. MANGIN (*Bul. Soc. Mycol. France, 15 (1899), No. 2, pp. 108–126, figs. 6*).—The parasitism of this fungus is claimed to be established and much injury may be traced to its presence on the wheat.

Recent studies on the brown rusts of cereals, J. ERIKSSON (*Ann. Sci. Nat. Bot.,* *3. ser., 9 (1899), Nos. 2–4, pp. 241–256; 5–6, pp. 257–290, pls. 3).*—Gives an account of the author's recent investigations. Essentially the same as a previous publication (E. S. R., 11, p. 554).

The Puccinias of the type P. hieracii occurring on Compositæ, E. Jacky (*Ztschr. Pflanzenkrank., 9 (1899), Nos. 4, pp. 193–224; 5, pp. 263–295, figs. 19*).—Discusses the life history and specialization of the species of Puccinia of this type.

Notes on the Æcidia occurring on the Umbelliferæ, O. Juel (*Oefv. Kgl. Vet. Akad. Förhandl., 1899, No. 1, p. 5; abs. in Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 20, pp. 689, 690*).

On the identity of Ustilago virens and U. oryzæ, J. Omori (*Bot. Mag. [Tokyo], 10 (1899), No. 110, pt. 2, pp. 29, 30; abs. in Bot. Centbl. Beihefte, 9 (1899), No. 1, p. 5*).—The author claims that these species are not identical as has been supposed by a number of other investigators.

The smuts of Cynodon dactylon and their distribution, P. Magnus (*Bul. Soc. Mycol. France, 15 (1899), No. 4, pp. 265–271, pl. 1*).—Notes are given on a number of species of Ustilago which are parasitic on *Cynodon dactylon*. Among those described are *U. paraguariensis, U. cynodontis*, and *U. dregeana*.

Sorghum blight, M. Radais (*Bul. Soc. Mycol. France, 15 (1899), No. 2, pp. 82–89*).—The author discusses the cause of sorghum blight and concludes that it is due, at least in part, to certain yeasts. Details are given of his experiments to isolate the yeasts, their characteristics are described, and the parasitism of the organism as shown by inoculation experiments is affirmed.

The fungus foes of fruits, B. D. Halsted (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 482–501, figs. 11*).—Popular notes are given on a number of the more common parasitic diseases of the apple, pear, peach, plum, cherry, and grape, together with suggestions for their prevention. Notes are also given on a number of parasitic diseases of small fruits.

Notes on some of the mildews which occur on fruit trees (*Gartenflora, 49 (1900), No. 3, pp. 58–60, figs. 3*).

Gooseberry mildew held in check, F. H. Hall and C. P. Close (*New York State Sta. Bul. 161, popular ed., pp. 4, fig. 1*).—A popular edition of Bulletin 161 of the station (see p. 945).

Plant diseases due to Monilia, P. Sorauer (*Ztschr. Pflanzenkrank., 9 (1899), No. 4, pp. 225–235, pl. 1, fig. 1*).—An account of an attack on the apple is described.

Morphological variations of Monilia due to the influence of culture media, F. Guéguen (*Bul. Soc. Mycol. France, 15 (1899), No. 4, pp. 271–279, figs. 15*).—Describes a number of variations from normal growth that are attributed to the culture media in which the fungus was grown.

Concerning the Monilia disease, P. Sorauer (*Ber. Deut. Bot. Gesell., 17 (1899), No. 6, pp. 186–189*).—Discusses Monilia as a cause of disease in a number of plants.

A spot disease of olives in Portugal, V. d'Almeida (*Bul. Soc. Mycol. France, 15 (1899), No. 2, pp. 90–94, figs. 2*).—Describes a disease of olive fruits due to *Glœosporium olivarum*.

Concerning a sclerotium disease of the quince, H. C. Schellenberg (*Ber. Deut. Bot. Gesell., 17 (1899), No. 6, pp. 205–215, pl. 1*).

Bladder rust of Pinus strobus, C. B. Plowright (*Gard. Chron., 3. ser., 26 (1899), No. 657, p. 94*).—Gives an account of successful transfer of æcidiospores of *Peridermium strobi* to currant leaves on which the uredo stage was noted within 3 weeks. The experiments were made in 1893.

A disease of ornamental conifers, W. G. Smith (*Gard. Chron., 3. ser., 26 (1899), No. 672, p. 354*).—A disease of *Biota orientalis* due to *Pestalozzia funerea* is described. A number of other conifers are attacked and the most evident symptom of the disease is the withering of twigs and branches in otherwise healthy trees. The parasitism of the fungus is asserted, but more information regarding the method of infection is needed. Defective cultivation, unsuitable soil and climate are supposed to weaken the plant and assist in presenting the proper conditions for the disease.

On the determination of the fungi which attack forest trees in India, J. S. Gamble (*Indian Forester, 25* (*1899*), *No. 11, pp. 431–438*).—Notes are given on a number of parasitic and saprophytic fungi on Indian forest trees.

The parasites of the trees in the Cambre forest, P. Nypels (*Ann. Soc. Belge Micros., 24* (*1899*), *pp. 7–46, pls. 2*).

Cultures of Nectria, or parasitic tree canker, Bra (*Compt. Rend. Acad. Sci. Paris, 129* (*1899*), *No. 2, pp. 118–120*).—Notes are given on cultures made of *Nectria ditissima.* The character of the fungus as grown on nutrient media is described at some length, and analogies between the cultures of this parasite and that causing cancer of human beings are pointed out.

An injurious effect of Bordeaux mixture, R. Thiele (*Ztschr. Pflanzenkrank., 9* (*1899*), *No. 4, pp. 235, 236*).—Gives an account of injury to pear foliage and fruit, due to the use of too strong solutions.

Recent studies of Bordeaux mixture (*Ztschr. Pflanzenkrank., 9* (*1899*), *No. 5, pp. 317–320*).—Compiled information relating to the making and application of Bordeaux mixture.

ENTOMOLOGY.

Proceedings of the eleventh annual meeting of the Association of Economic Entomologists (*U. S. Dept. Agr., Division of Entomology Bul. 20, n. ser., pp. 111, figs. 4*).—At this meeting, held in Columbus, Ohio, August 18 and 19, 1899, the following papers were read:

The laisser faire philosophy applied to the insect problem, C. L. Marlatt (pp. 5–19).—This paper constitutes the annual address of the president of the association. The author states his belief to be that quarantine laws by State or National authority will ultimately prove ineffective in preventing the introduction or spread of injurious insects, and that no insect, when once introduced into a country, can be entirely exterminated by artificial means. He gives popular accounts of the more common theories which have been suggested to account for the increased activity of introduced insects. It is suggested that the economic entomologist should properly confine his efforts to discovery and application of more effective practical methods, rather than attempt to prevent the further distribution of injurious insects.

A remedy for gadflies: Porchinski's recent discovery in Russia, with some American observations, L. O. Howard (pp. 24–28).—An abstract of Porchinski's paper, which has been previously abstracted (E. S. R., 11, p. 653).

The present status of the caprifig experiments in California, L. O. Howard (pp. 28–35).—The author gives a brief account of the work of the fig insect, *Blastophaga grossorum*, in fertilizing the Smyrna fig of commerce. A number of unsuccessful attempts to introduce this insect into California have been made within the past few years. In the spring of 1899, the Division of Entomology imported some fig insects and they were successfully colonized in California. The insects have bred abundantly for one generation. These experiments have shown that it is possible to introduce the fig insect into California, and it remains now to determine whether the time of appearance of different broods of the insect will be so changed in California as to require other importations before making a permanent colonization of the fig insect.

The original home of the San José scale, L. O. Howard and C. L. Marlatt (pp. 36–39).—From a study of the literature of the subject and of cases of supposed original importation of the San José scale from Japan, the authors conclude that the evidence is not conclusive and that it would be quite as reasonable to suppose that the scale was carried from America to Japan as to suppose that it was originally imported into America from Japan.

Voluntary entomologic service in New York State, I. P. Felt (pp. 39–43).—The author reports the results of requesting reports from voluntary observers in different parts of the State. A number of these observers had reported regularly each week regarding the relative numbers of various injurious insects, and the author believes that such information will be of considerable value.

The Emory fumigator: A new method for handling hydrocyanic-acid gas in orchards, W. G. Johnson (pp. 43–45).—The use of duck tents for covering trees was considered too expensive for the average fruit grower, and a cheaper apparatus for fumigation was therefore devised. This apparatus is in the form of a box covered with rawhide paper, except the top, to which a hood of duck was adjusted. The box was lifted over the tree and the duck hood then adjusted to the top. In introducing the chemicals the box was slightly tilted. For larger trees it was found advisable to construct the box with hinges so that it could be opened and placed around the tree. This apparatus was about two-thirds as expensive as the ordinary duck tent used for fumigating purposes.

Insectary and office methods, F. M. Webster (pp. 46–52).—A general discussion of methods of collecting and rearing insects, and of management of this material after it is mounted, together with the keeping of records and mapping of distribution areas.

A probable remedy for the cranberry fireworm, A. H. Kirkland (pp. 53–55).—The larvæ of *Rhopobota vacciniana* causes considerable damage to the cranberry crop of Massachusetts. The larvæ of the first brood seldom cause much injury, while those of the second brood are often exceedingly destructive. Where the cranberry bogs can be flooded with water at the proper season for destroying the larvæ, this method is very effective, but in many cases it is impossible to use water in this way. Experiments were tried with arsenate of lead, which was used as a spray at the rate of 9 lbs. to 150 gal. of water. The first application was made in the early part of June. The second brood of caterpillars appeared during the first part of July, and a second application was made, the insecticide being used at the rate of 13½ lbs. to 150 gal. of water. Nearly all the larvæ were destroyed, and a great saving in the cranberry crop was the result of this method. It was found that three men with a good outfit could spray 8 acres of cranberry bog in 10 hours.

An interesting outbreak of chinch bug in northern Ohio, F. M. Webster (pp. 55, 56).—The chinch bug had been reported in 1886 from Huron County, Ohio. In the spring of 1899 this region was visited and was found to be more or less seriously infested with the short-winged form of the chinch bug.

Some insects of the year in Georgia, A. L. Quaintance (pp. 56–60).—Brief biological and economic notes upon the following insects: *Cerotoma trifurcata*, *Diabrotica vittata*, *Doryphora 10-lineata*, *Diabrotica 12-punctata*, *Allorhina nitida*, *Monocrepidius vespertinus*, *Ithycerus noveboracensis*, *Amphicerus bicaudatus*, *Scolytus rugulosus*, *Heliothis armiger*, *Diatræa saccharalis*, *Margaronia nitidalis*, *M. hyalinata*, *Plutella cruciferarum*, *Pieris rapæ*, *P. protodice*, *Plusia brassicæ*, *Pionea rimosalis*, *Aphis brassicæ*, *Spilosoma virginica*, *Phlegethontius celeus*, *Aphis gossypii*, *Murgantia histrionica*, *Melittia satyriniformis*, and *Anasa tristis*.

Notes of the year for New York, E. P. Felt (pp. 60–62).—A brief account of the following noxious insects: *Euvanessa antiopa*, *Systena frontalis*, *Clisiocampa disstria*, *Galerucella luteola*, *Crioceris 12-punctata*, and *Cicada septendecim*.

Miscellaneous entomological notes, W. G. Johnson (pp. 62–68).—The author gives a brief report of the depredations of the following injurious insects: *Nectarophora destructor*, *Crambus caliginosellus*, *Systena tæniata blanda*, *Myodocha serripes*, *Odontota dorsalis*, *Lygus pratensis*, *Pemphigus acerifolii*, *Psylla pyricola*, *Pteronus ribesii*, *Conotrachelus nenuphar*, *Anthonomus signatus*, *Haltica chalybea*, *Cecidomyia destructor*, *Notolophus leucostigma*, *Thyridopteryx ephemeræformis*, *Colopha ulmicola*, *Sphinx catalpæ*, *Galerucella luteola*, *Datana integerrima*, *Aphis gossypii*, *A. forbesi*, *A. prunicola*, *Diabrotica vittata*, *Aspidiotus perniciosus*, *Lecanium nigrofasciatum*, *Mytilaspis pomorum*, *Chionaspis furfurus*, *Tribolium confusum*, *Ephestia kuehniella*, *Tenebroides mauritanicus*, *Silvanus surinamensis*, *Murgantia histrionica*, *Crioceris asparagi*, *Plusia brassicæ*, *Pieris rapæ*, *Doryphora 10-lineata*, and *Epicauta vittata*.

Insects of the year in Ohio, F. M. Webster and C. W. Mally (pp. 68–73).—Brief notes on the following insects: *Diplosis tritici*, *Diabrotica longicornis*, *Thrips tabaci*, *Epicauta vittata*, *Melanoplus bivittatus*, *Fidia viticida*, *Macrodactylus subspinosus*, *Exartema permundana*, *E. fasciata*, *Oxyptilus tenuidactylus*, *Colaspis brunnea*, *Crioceris asparagi*, *Murgantia histrionica*, *Selandria vitis*, *Eudemis botrana*, *Hadena devastatrix*, *Lygus pratensis*, *Chramesus icoriæ*, *Gymnetron teter*, *Agromyza æneiventris*, and *Laverna gleditschiella*.

Temperature control of scale insects, C. L. Marlatt (pp. 73–76).—The author believes that either a cold damp climate or an excessively hot and dry climate is unfavorable to the development of scale insects, while a climate which presents a moderate amount of heat and moisture is most favorable for the growth and multiplication of these insects. It is suggested that possibly the scale covering is less dense in warm latitudes than in colder climates, and that consequently scale insects suffer more severely from a sudden fall in temperature in the former than in the latter regions.

An account of Aspidiotus ostreæformis, C. L. Marlatt (pp. 76–82, figs. 4).—This article is the same in its essential features as an article previously abstracted (E. S. R., 11, p. 274).

Fatal temperature for some coccids in Georgia, W. M. Scott (pp. 82–85).—The main facts of this article were previously published by the author in his report as State entomologist (E. S. R., 11, p. 368).

The destruction of hairy caterpillars by birds, E. H. Forbush (pp. 85–93).—Thirty-eight different observers have made reports upon the feeding habits of birds with reference to hairy caterpillars, and these reports are briefly summarized in the present paper. The author believes that actual observation of the feeding habits of birds in the field furnishes valuable evidence to supplement the results obtained in the study of the contents of birds' stomachs. The present paper is confined largely to observations made upon the gypsy moth, the brown-tail caterpillar, the tent caterpillar, and the forest tent caterpillar. The hairs of the brown-tail caterpillar are of the stinging sort and produce painful irritation when they come in contact with the hand. The caterpillars were eaten, however, in large numbers by various species of birds. A list of birds is given which includes those that have been actually observed feeding upon hairy caterpillars. The list includes 46 species.

The destructive pea louse, a new and important economic species of the genus Nectarophora, W. G. Johnson (pp. 94–98).—In May, 1899, the author's attention was first called to the destructive work of a plant louse which, upon investigation, proved to be a new species and which is called *Nectarophora destructor.* The insects attack the young pea-vines and multiply with such rapidity that the vines are often killed outright. The insects have also been found upon sweet peas. From the method which is usually adopted in cultivating peas, it is evident that the discovery of an effective remedy would be a difficult matter. It was found that a 15 to 30 per cent solution of kerosene and water destroyed the insects very thoroughly. Whale-oil soap and tobacco dust were also effective, but these remedies are expensive as applied to pea fields. The author found that a large proportion of the plant lice were destroyed by their insect enemies. Among these enemies the most important were the syrphus flies, the lady beetles, and lace-winged flies. In some instances the syrphus flies were present in very unusual numbers. No hymenopterous parasites were reared from the plant lice. A few of the plant lice died of what appeared to be a bacterial disease, but this matter is not yet determined.

The stalk worm: A new enemy to young tobacco, W. G. Johnson (pp. 99–102).—The larvæ of *Crambus caliginosellus* were found eating the stems of tobacco just at the surface of the ground or boring in the stems. Ordinarily but one larva was found in a single stem. The insects attacked corn and were very destructive to this crop, as well as to tobacco. The author believes that this insect is most likely to be found in tobacco fields which were previously sown to timothy or other grass, and recommends, therefore, that tobacco growers avoid planting tobacco upon grass or timothy sod.

An improvement in the manufacture of arsenate of lead, *A. H. Kirkland* (pp. 102, 103).—It was found that by using nitrate of lead in the place of acetate of lead for neutralizing the arsenate of soda, a larger percentage of arsenic was obtained and at a smaller cost.

Recent work against the gypsy moth, *E. H. Forbush* (pp. 104–107).—The State of Massachusetts has expended $1,155,000 in its warfare against the gypsy moth. During 1899 most attention was paid to burlapping, and about 2,500,000 trees were burlapped during the season. New colonies of the gypsy moth were discovered in Newton and Georgetown.

A destructive tan-bark beetle, *A. F. Burgess* (pp. 107, 108).—The larvæ of *Dinoderus substriatus* were found in great numbers in piles of tan bark which had been purchased in Nova Scotia in 1897. It was recommended that the tan bark be fumigated, but the expense was considered by the owners to be too great, and the infected bark was therefore ground up as quickly as possible.

Some insects of the year 1898, R. H. PETTIT (*Michigan Sta. Bul. 175, pp. 341–373, figs. 20*).—This bulletin contains brief economic notes on the following insects: *Schistocerca americana*, *Thrips tabaci*, *Brochymena annulata*, *Phoxoptera comptana*, *Depressaria persicæella*, *Clisiocampa disstria*, *Empretia stimulea*, *Aspidisca splendoriferella*, *Lithocolletis lucetiella*, *L. cincinnatiella*, *Pegomyia vicina*, *Cecidomyia destructor*, *Chrysomela suturalis*, *Magdalis armicollis*, *Scolytus rugulosus*, *Harpiphorus maculatus*, *Bruchophagus funebris*, *Neuroterus q-saltatorius*, and *Camponotus pennsylvanicus*.

The larvæ of *Depressaria persicæella* were found to feed to a considerable extent upon the leaves of peaches. They form loose nests by binding the peach leaves together with a fine silk thread. The larvæ were observed on July 3 and also on September 17, and are therefore probably two brooded. The insect was referred to Miss M. E. Murtfeldt, and she considered it a new species. Her description is included in the author's account. Among artificial remedies the author recommends spraying with Paris green, and destruction of the nests which are sufficiently conspicuous to render their detection easy.

The author found that the larvæ of *Aspidisca splendoriferella* in tying up their cases for the winter did not attach them to cherry leaves, but almost without exception to evergreen trees near at hand or to the twigs and bark of the cherry.

As a means for combating *Magdalis armicollis* the author recommends the use of trap poles of green elm to be set in the ground near the trees which one wishes to protect. These insects preferably lay their eggs in dying trees, and are led to deposit them in such trap poles and may thus be destroyed by burning the poles.

The author gives formulas and directions for the use of various insecticides, including whale-oil soap, pyrethrum, hellebore, arsenite of lead, Paris green, and carbon bisulphid. Some experiments were conducted in the treatment of beet seed with this latter substance. Four lots of seed were treated in different ways. Lot No. 1 was exposed for 24 hours to the action of the gas used at a rate of 2 dr. of liquid to a cubic foot of space. Lot 2 was exposed for 24 hours to an atmosphere saturated with the gas. Lot 3 was untreated and reserved as a check upon the others. Lot 4 was exposed for 48 hours to an atmosphere saturated with the gas. In lot 1, 93 per cent of the seeds germinated at the end of two weeks; in lot 2, 76 per cent germinated; in lot 3, which was the check, 93 per cent germinated; and in lot 4, 50 per cent germinated. Exposure to the gas at a rate of 2 dr. of liquid to the cubic foot of space seemed to accelerate the germination without injuring the seed.

Supplementary report of the zoologist, H. T. FERNALD (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 373–443, figs. 19*).—Since very little literature on the economic entomology of Pennsylvania is available for the farmers of the State, the author has undertaken the preparation of brief popular accounts of a large number of injurious insects. Under the head of insects injurious to wheat, economic and biological notes are given on the following insects: The Hessian fly, the wheat midge, the wheat-stem maggot, the jointworm, the wheat-stem sawfly, the army worm, wireworms, grain aphis, Angoumois grain moth, and the granary weevil. These insects are for the most part figured, and brief descriptions are given of their appearance, habits, life history, and the remedies which have proved most effective against them.

Under the caption "cabbage insects" (p. 393), the author discusses the following insects from an economic standpoint: Cabbage worm, zebra caterpillar, the cabbage-root maggot, and the harlequin cabbage bug.

Under the head of "fruit insects" (p. 403), the following insects are discussed: The codling moth, the apple tree tent caterpillar, the cecropia moth, the round-headed apple-tree borer, peach-tree borer, peach-twig borer, and plum curculio.

The author has devoted some attention to household insects, and under this head (p. 418) has given an account of the following insects: The buffalo beetle, the black carpet beetle, clothes moths, cockroaches, and ants.

A discussion of a few miscellaneous insects is given in a separate section (p. 426), including economic accounts of the following species: The corn worm, the walking stick, the rose chafer, and the striped cucumber beetle.

Formulas are given (p. 435) for the preparation of some of the more common insecticides, such as Paris green, London purple, arsenate of lead, kerosene emulsion, whale-oil soap, Bordeaux mixture, and ammoniacal copper carbonate.

The author gives a brief discussion of the relationship between parasites and their hosts It is contended that parasites can not be depended upon to exterminate the host insects, but they may have the effect of checking their sudden unlimited multiplication. The Catalpa sphinx (*Ceratomia catalpæ*) is reported as having caused considerable damage to Catalpa trees near Media. The author recommends that this insect be controlled by the use of a Paris green spray upon such trees as are not too large and by the collection of the egg masses.

The pear and apple-leaf blister moth, F. V. THEOBALD (*Jour. Southeast Agr. Col., Wye, 1899, No. 8, pp. 21–31, figs. 5*).—The author gives a general account of the damages caused by this species, *Cemiostoma scitella.* The plants upon which the insect depredates are the sloe, hawthorn, apple, pear, and mountain ash. The insect seems to show a preference for the hawthorn, but is quite injurious to the apple and pear. The larvæ mine in the leaves of these trees and produce rather regular blotches, which are most conspicuous on the upper surface of the leaf. These blotches attain a diameter of one-half inch. The attack upon the leaves begins during the latter part of May, but is most active in July and August. The insect is apparently two brooded, the adult appearing at the end of April and again in June and July. The author describes and figures the various stages of this insect, and gives a brief account of its geographical distribution.

Paraffin and soap were sprayed upon the leaves without any effect. Arsenate of lead sprayed upon the leaves at about the time when the eggs are deposited seemed to have a beneficial effect.

The relation of honeybees to practical horticulture, W. R. LAZENBY (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 149–154*).—In this paper the author records a number of observations upon the activity of bees in visiting the flowers of cultivated fruits. It was observed that the red raspberry was visited most frequently by bees and that other fruits were visited less frequently, as in the following series: Blackberry, plum, cherry, black-cap raspberry, apple, gooseberry, peach, pear, currant, and strawberry. Tables are presented, giving the weights of outgoing bees, honey-collecting bees, and pollen-laden bees.

Dickel's theory on the development of bees, A. THUMA (*České Listy Hospodářské, 7 (1899), No 7, pp. 261–265*).—A general discussion of the arguments for and against the parthenogenetic origin of drones.

Some harmful household insects, H. T. FERNALD (*Pennsylvania Dept. Agr. Bul. 48, pp. 13, figs. 2*).—This is a reprint from Pennsylvania Department of Agriculture Report for 1898, pt. 1, p. 118.

Notes on Ohio insects injurious to stored vegetable products, J. S. HINE (*Jour. Columbus Hort. Soc., 14 (1899), No. 3, pp. 120, 121*).—Brief notes on a number of insects which were observed to be injurious to stored vegetable products in Ohio.

The zonal distribution of Coleoptera, T. D. A. COCKERELL (*New Mexico Sta. Bul. 28, pp. 135–179*).—This bulletin is a continuation of Bulletin 24 of the station (E. S. R. 10, p. 324), and contains tables which show the distribution of the different families of Coleoptera, with the exception of the Cicindelidæ and Carabidæ. The region in which these insects were found is believed to belong to the Upper Sonoran Life Zone.

The insects of the year, F. L. HARVEY (*Maine Sta. Rpt. 1898, pp. 125–130*).—Brief notes on a number of common injurious insects.

Report of the entomologist, H. TRYON (*Queensland Dept. Agr. Rpt. 1898–99, pp.*

34–39).—In this report the author gives brief notes on the injurious insects of a great variety of economic plants. Good success is reported in connection with experiments in trapping the grub pest of sugar cane.

Farm pests, J. Fletcher (*Ottawa: S. E. Dawson, 1899, pp. 20*).—This pamphlet presents brief, popular accounts of the following insects: Tent caterpillar, San José scale, Rocky Mountain locust, wheat-stem maggot, cabbage-root maggot, pea moth, carrot rust fly, turnip aphis, gray fruit worm, and codling moth. The remedies which have been found effective in each case are recommended for use.

Insects, J. M. Southwick (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 83–94, figs. 6*).—This paper contains notes on the potato beetle, cankerworm, codling moth, and tent caterpillar, with general directions for spraying and formulas for making Paris-green spray and kerosene emulsion.

A contribution to the study of mosquitoes, G. Noè (*Bul. Soc. Ent. Ital., 31 (1899), No. 1–4, pp. 235–262*).—This account contains descriptive and biological notes on the following species of mosquitoes: *Culex ficalbii, C. mimeticus, C. malariæ, C. pulchritarsis, C. albopunctatus,* and *C. nemorosus.*

Twenty species of Italian Culicidæ, E. Ficalbi (*Bul. Soc. Ent. Ital., 31 (1899), No. 1–4, pp. 46–234, figs. 89*).—In this article the author discusses methods of collecting and preserving mosquitoes and gives a general characterization of the family Culicidæ. Detailed notes by way of description and accounts of the habits and life history and economic importance of 20 species of Italian Culicidæ are given. These species belong to the genera Anopheles and Culex. The author also discusses the geographical distribution of the species. The following species are treated in this article: *Anopheles pseudopictus, A. superpictus, A. claviger, A. bifurcatus, Culex penicilliaris, C. ornatus, C. cantans, C. vexans, C. nemorosus, C. pulcritarsis, C. albopunctatus, C. annulatus, C. glaphyropterus, C. spathipalpis, C. richiardii, C. elegans, C. pipiens, C. modestus, C. impudicus,* and *C. hortensis.*

White grubs and the productiveness of meadows, R. Santrucek (*České Listy Hospodářské, 7 (1899), Nos. 5, pp. 168–170; 6, pp. 217, 218*)—The larvæ of a species of Melolontha were observed to attack *Bromus erecta, Aira cæspitosa,* Rumex, Scabiosa, Salvia, etc. The larvæ were parasitized by a species of Botrytis.

The clover-root mealy bug, R. H. Pettit (*Canad. Ent., 31 (1899), No. 10, pp. 279, 280, fig. 1*).—Notes on *Dactylopius trifolii.*

Some insects injurious to wheat, H. T. Fernald (*Pennsylvania Dept. Agr. Bul. 46, pp. 24, figs. 7*).—This is a reprint from Pennsylvania Department of Agriculture Report for 1898, pt. 1, p. 374.

Common cabbage insects, H. T. Fernald (*Pennsylvania Dept. Agr. Bul. 48, pp. 14, figs. 3*).—This is a reprint from Pennsylvania Department Agriculture Report 1898, pt. 1, p. 393.

Cranberry pests and how to combat them, J. S. Bishop (*Fruit Growers' Assoc. Nova Scotia Rpt. 1899, pp. 99–103*).—Notes on the fireworm, fruit worm, and the cranberry spanworm. Against the fireworm the author recommends the following remedies: Flooding the vines in June for 60 hours; spraying with tobacco, Paris green, or arsenate of lead for the fruit worm, spraying with Paris green just after the setting of the berries; for the spanworm, it is recommended that the vines be sprayed with Paris green or arsenate of lead.

Descriptions of Australian Curculionidæ with notes on previously described species, A. M. Lea (*Trans. Roy. Soc. South Australia, 23 (1899), No. 2, pp. 137–197*).

Some insects attacking fruit and fruit trees, H. T. Fernald (*Pennsylvania Dept. Agr. Bul. 47, pp. 19, figs. 5*).—A reprint from Pennsylvania Department of Agriculture Report for 1898, pt. 1, p. 403.

Notes on two new species of Aphids, G. B. Buckton (*Indian Mus. Notes, 4 (1899), No. 5, pp. 277, 278, pl. 1*).—*Chaitophorus maculatus* attacks *Medicago sativa* in India, and *Rhizobius jujubæ* is injurious to the roots of *Zigyphus jujuba.*

The pear-tree aphis (Lachnus pyri), G. B. Buckton and E. E. Green (*Indian Mus. Notes, 4 (1899), No. 5, pp. 274–276, pl. 1*).—This insect is reported as very injurious to pear trees in parts of Ceylon. Large quantities of honeydew are secreted by this species and the branches and trunks of the trees become covered with this substance. The insect appears to be viviparous. The attack is made on stems and branches, and the authors recommend the use of soap washes against the insect.

Some injurious scale insects, W. NEWELL (*Iowa Sta. Bul. 43, pp. 145–176, figs. 21*).—In this bulletin the author has given brief descriptions and an account of the life history, habits, and economic importance of the following insects: *Chionaspis furfurus, C. americana, C. ortholobis, C. salicis, C. pinifolii, Diaspis rosæ, Mytilaspis pomorum, Aspidiotus ancylus, A. forbesi, A. perniciosus, A. osborni, A. ficus, A. rapax, A. hederæ, Lecanium* spp., *Pulvinaria innumerabilis, Dactylopius longifilis*, and *D. destructor*.

Illustrations are given in the text of the majority of these insects. The author gives formulas and suggestions concerning the making and application of the insecticides which are in more common use against scale insects.

Three common orchard scales, J. B. SMITH (*New Jersey Stas. Bul. 140, pp. 16, figs. 9*).—This bulletin gives a popular account of the life history, habits, and means of controlling the oyster-shell bark-louse, scurvy scale, and San José scale. Among the remedies recommended against the San José scale, and against scale insects in general, may be mentioned whale-oil soap, kerosene, either diluted with water or in pure condition, and crude petroleum.

Chrysomphalus ficus and C. minor, P. MARCHAL (*Reprint from Bul. Soc. Ent. France, 1899, No. 15, pp. 3*).—These scale insects are reported by the author as having been recently introduced into Algeria and apparently established there.

The San José scale and other scale insects, H. T. FERNALD (*Pennsylvania Dept. Agr. Bul. 43, pp. 20, figs. 9*).—This bulletin contains a general account of the appearance, life history, food habits, distribution, and remedies to be adopted against the following insects: San José scale, oyster-shell bark-louse, scurvy scale, peach diaspis (*Diaspis lanatus*), *D. rosæ, Aspidiotus juglans-regiæ, A. ancylus*, and *Lecanium persicæ*.

American fruit and San José scale, K. POLAK (*České Listy Hospodářské, 6 (1898), No. 6, pp. 214–217, figs. 6*).—Brief notes on San José scale and a number of other related scales as occurring on American fruit.

The San José scale and related species, H. LOHMANN (*Schr. Naturw. Ver. Schleswig-Holstein, 11 (1898), No. 2, pp. 274–279*).—Brief notes on *Aspidiotus ostreæformis, Porphyrophora polonica, Coccus cacti, C. lacca*, etc.

Insect pests amendment act, 1898 (*Jour. Dept. Agr. West. Australia, 1899, Dec., pp. 15–17, figs. 3*).—Notes on the San José scale, fruit fly, and the inspection of packing cases.

The workings of the San José scale law, S. A. FORBES (*Trans. Illinois Hort. Soc., n. ser., 33 (1899), pp. 150–159*).—According to an Illinois law approved in April, 1899, the State entomologist is required to inspect all nurseries in the State once each year. A tolerably complete list of nurseries was secured and 4 inspectors have been placed in the field in different parts of the State. Considerable treatment of trees has been done both by spraying and fumigation. The author believes that the law is a good one and that its enforcement will be to the advantage of horticulture in the State.

An injurious caddice fly, F. L. HARVEY (*Maine Sta. Rpt. 1898, pp. 122–124*).—A caddice fly belonging to the genus Limnephilus is reported as having caused great damage to water lilies. The larvæ were rather thoroughly checked by handpicking and no further trouble has resulted from their attacks.

Notes on and descriptions of the male of Cœlostoma immane and of a new species of leaf-mining moth, J. G. O. TEPPER (*Trans. Roy. Soc. South Australia, 23 (1899), No. 2, pp. 278–280*).—*Nepticuea nigricansella* is reported as injuring the leaves of *Kennedya nigricans*.

Description of a new parasitic Tachinid fly from Ceylon, D. W. COQUILLETT (*Indian Mus. Notes, 4 (1899), No. 5, p. 279, pl. 1*).—*Exorista heterusiæ* is described as a parasite bred from *Heterusia cingala*.

Injurious millipedes, F. L. HARVEY (*Maine Sta. Rpt. 1898, pp. 118-121, pl. 1*).—*Polydesmus monilaris* and *Iulus hortensis* were observed during various stages of their development feeding upon radishes. Their attacks caused excrescences upon the exterior of the radishes. A number of other species of myriapods were observed in the greenhouses, but were not seen in the act of injuring radishes. Brief descriptions and biological notes are given concerning the 2 species mentioned, as well as of *Iulus virgatus*, *Paraiulus immaculatus*, and *Orthomorpha gracilis*. As remedies against these pests the author recommends hand picking. It is stated that more injury is done in subirrigated than in surface watered beds.

Combating the animal parasites of cultivated plants by means of their natural enemies, A. ZIMMERMANN (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), Nos. 23, pp. 801-809; 24, pp. 838-841*).—The author gives a review of the literature of the subject, together with a bibliography. The question is treated under the following heads: The natural enemies belonging to the animal kingdom, protection and artificial breeding of natural enemies, and importation of natural enemies from foreign countries. Special attention is given *Icerya purchasi*, *Aspidiotus perniciosus*, *Lecanium viride*, *Phylloxera vastatrix*, etc.

Annual report of the instructor in fruit culture, A. H. BENSON (*Queensland Dept. Agr. Rpt. 1898-99, pp. 39-44*).—The author reports on experiments in the use of hydrocyanic gas and the destruction of scale insects, and upon work in controlling the San José scale. In fighting this insect, the author painted the trees with sulphate of lime thickened with fine flour, and followed this treatment with a kerosene emulsion spray. A mixture of sulphid of soda and whale-oil soap also proved effective.

Methods for the protection of crops from insects and fungi, H. T. FERNALD (*Pennsylvania Dept. Agr. Bul. 49, p. 20*).—A brief outline of methods to be adopted in protecting field and garden crops from common insect and fungus diseases.

The timely plowing of stubbles and its influence upon certain diseases of cereals, M. HOLLRUNG (*Jahresber. Vers. Stat. Pflanzenschutz, Halle, 10 (1898), pp. 29-34*).—The author discusses the influence of this method in controlling diseases of cereals caused by *Oscinis frit*, *Cecidomyia destructor*, *Heterodera schachtii*, grain aphis, *Cephus pygmæus*, *Thrips cerealium*, and the fungi *Leptosphaeria herpotrichoides*, *Ophiobolus herpotrichus*, and species of Septoria.

The author concludes that, where it is possible, the stubble should be plowed under deeply immediately after the harvest.

Disinfection of grape stock against phylloxera (*Messager Agr., 4. ser., 10 (1899), No. 12, pp. 473, 474*).—Recommends immersion for five minutes in water at 53° C.

Recent developments in spraying, F. C. SEARS (*Fruit Growers' Assoc. Nova Scotia, Rpt. 1899, pp. 16-19*).—Notes on the preparation and application of insecticides and on the San José scale.

Modern methods of spraying, A. H. KIRKLAND (*Appendix Maine Bd. Agr. Rpt. 1898, pp. 69-79*).—A popular account of insecticides and spraying machines, with directions for treatment against some common injurious species of insects.

FOODS—ANIMAL PRODUCTION.

Experiments upon the digestibility of bread with men, C. D. WOODS and L. H. MERRILL (*Maine Sta. Rpt. 1898, pp. 173-195*).—In cooperation with this Department a number of experiments were made on the digestibility by man of white bread and milk, graham bread and milk, and entire-wheat bread and milk. In some of the experiments butter and sugar were also eaten. The experiments were conducted by the usual methods. The balance of income and outgo of nitrogen was also determined. (See following abstract.)

The digestibility of bread, C. D. WOODS and L. H. MERRILL (*Maine Sta. Rpt. 1898, pp. 196-207*).— Assuming that 98 per cent of the protein and carbohydrates, 99 per cent of the fat in milk, 99 per cent of the fat in butter, and 98 per cent of the carbohydrates in sugar is digestible, the authors calculate the digestibility of bread alone in the experiments noted in the article above, when the bread was consumed as part of a mixed diet. In these experiments the fuel value of the food and feces was determined and the heat of combustion of the urine was calculated. Making use of the data obtained, the percentage of energy of the food which was utilized in the body was calculated. The average results of all the experiments follow:

Digestibility of different kinds of bread by man

Kinds of food	Protein	Fat	Carbohydrates	Heats of combustion.
	Per cent	*Per cent*	*Per cent*	*Per cent*
White bread alone (average of 4 experiments)	82.0	70.7	98.4	92.2
White bread consumed with milk (average of 9 experiments)	88.3	66.6	98.2	94.8
Graham bread consumed with milk (average of 6 experiments)	77.0	58.1	92.4	88.0
Entire wheat bread consumed with milk (average of 5 experiments)	86.6	46.2	97.2	94.0

Skimmed milk vs. water in bread making, C. D. WOODS and L. H. MERRILL (*Maine Sta. Rpt. 1898, pp. 213–218*).—According to the authors skim milk is not usually appreciated in the household. Its comparatively high food value is pointed out, as well as the fact that it may be profitably used in making bread and other articles of diet. The composition of bread made with water and with skim milk was determined. The average results follow:

Composition of bread made with water and with skim milk.

Kind of bread	Water	Protein (N × 6.25)	Fat	Carbohydrates *a*	Carbohydrates *b*	Ash	Heats of combustion determined
	Per ct	*Per ct*	*Per ct*	*Per ct*	*Per ct*	*Per ct*	*Calories*
Water bread (average of 3 analyses)	39.44	8.93	1.07	49.69	50.48	.87	*c*2,694
Skim milk bread (average of 3 analyses)	37.97	9.98	.94	49.82	50.72	1.29	*c*1,710

a Estimated by difference assuming protein = N × 6.25
b Estimated by difference assuming protein = N × 5.7
c Average of two determinations.

Work of Repsteiner and Spirig on the digestibility of bread made with water and with skim milk is quoted in detail (E. S. R., 9, p. 981), and experiments on the digestibility of such breads in a pepsin solution are reported. It was found that on an average 94.7 per cent of the bread made with water was digestible and 94.21 per cent of that made with skim milk.

"Skimmed-milk bread contains more protein (muscle-forming food) than water bread. Skimmed-milk bread is as completely digested as water bread. The use of skimmed milk in bread making utilizes a valuable waste product of the dairy."

Preservatives in canned foods offered for sale in North Carolina, W. A. WITHERS and H. W. PRIMROSE (*North Carolina Sta. Bul.*

165, pp. 369–374).—The authors examined a number of samples of canned goods. Of the 11 samples of fruit, all were found to contain preservatives, but no mention of this fact was made on the label. Of the 20 samples of vegetables examined, 12 were found to contain preservatives, and the fact was not mentioned on the label. One sample each of clams, sausage, steak, potted tongue, and 2 samples each of oysters and salmon were examined, but no added preservative was found.

"As a summary of the whole it may be stated that no added preservative was found in the canned meats, but that 100 per cent of the canned fruits and 60 per cent of the canned vegetables contained salicylic acid, and that 18 per cent of the fruits and 10 per cent of the vegetables contained in addition sulphurous acid.

"Metals were not tested for in all the samples, but they were found in several of those where tests were made for them.

"In view of these facts the wisdom of the State legislation on the subject of food adulteration is apparent."

Dietary studies of negroes in eastern Virginia in 1897 and 1898, H. B. Frissell and Isabel Bevier (*U. S. Dept. Agr., Office of Experiment Stations Bul. 71, pp. 45, pls. 3*).

Dietary studies among the negroes in 1897, H. B. Frissell (pp. 1–25.)—Dietary studies were made with 12 negro families in the region bordering the Great Dismal Swamp. Most of the families had very limited means.

Dietary studies among the negroes in 1898, Isabel Bevier (pp. 27–45).—The author reports 7 dietary studies of negro families residing in Elizabeth City County. Some of the families had been brought to a great degree under the influence of Hampton Institute. Others had not had the benefit of such training. In some instances the resources of the families were very limited; in other cases the income was fairly large. The studies in this and the preceding section of the bulletin are discussed in some detail and the results compared with those obtained in other regions.

Cost, nutrients, and fuel value of food per man per day in dietary studies in Virginia.

"It would seem that, judging solely by the amount of nutrients, the negro families in Virginia were on the average more abundantly fed than those studied in Alabama. [E. S. R., 9, p. 160.] The fuel value of the food was, if anything, more than sufficient for their daily needs, although the majority of the people studied were at active exercise in the fields. The quantity of protein was as large as is found in the average diet of the ordinary white person.

"It is interesting to note that in the negro families who had come more or less under the influence of Tuskegee and Hampton Normal institutes the diet was more or less modified. . . . The diet of these families resembles quite closely that of the ordinary white family under similar conditions, both as regards variety of food materials and as regards the amounts of nutrients. . . .

"The range in the quantity of nutrients per man per day in the different studies is much larger than is ordinarily found among families in very much the same conditions as were the families studied. A possible reason for this large variation was suggested by the observed fact that when there was plenty of food on hand large quantities were consumed by the different families, after which, during a period of less plentiful food, much smaller amounts would be consumed, without apparent discomfort or ill results."

Effects of borax and boracic acid on the human system, O. LIEBREICH (*London: J. and A. Churchill, 1899, pp. 44, pls. 2*).—In this article, which is translated from the German, the author summarizes the history of borax and boric acid, the uses of these materials in medicine, quotes the results of a number of experiments with men and animals, and reports experiments in which dogs, guinea pigs, and rabbits were fed different quantities of boric acid, bicarbonate of soda, and saltpeter; metabolism experiments with dogs fed boric acid; tests of the influence of borax, carbonate of soda, and saltpeter on the ferments of saliva; of borax, boric acid, and saltpeter on pepsin and hydrochloric acid; and of these materials and carbonate of soda on extract of pancreas and on emulsine. The effect of boric acid and borax on the ciliary epithelium of a frog, and of boric acid, borax (water-free), soda (water-free), saltpeter, and common salt on the gastric and intestinal epithelium of dogs was also tested. According to the author the use of borax in medicine has been generally found to be satisfactory. The following statements were made in connection with feeding experiments with borax:

"A dog of 12.2 kg. weight was given meat food with 5 gm. borax dry per day. On the 16th day, the dog having meanwhile gained 1 kg., symptoms of violent intestinal inflammation set in and continued for 5 days. There was severe hemorrhage, appetite diminished, and howling and whining indicated a condition of pain. The dosing was continued during this period. On the 5th day of illness the dog recovered and seemed quite lively. For 70 days longer it was fed with 5 gm. borax daily, making a total of 450 gm. borax within 90 days. At the end of this period it had gained 3.4 kg. in weight. This experiment shows conclusively that borax in too great concentration or given in substance, as was here the case, is able to call forth intestinal symptoms, but that, in spite of the phenomena of intestinal irritation, no toxic influence on the entire organism could be observed, a fact supported primarily by the increase in weight from 12.2 kg. to 15.62 kg., i. e., 2.8 per cent. Other alkalis are not known to be so mild in their influence on the animal organism.

"Experiments on rabbits prove that even [relatively] larger doses of borax repeatedly given are well borne if the solid salt be not used. A rabbit of 2,400 gm.

received twice, on the first day and the fifth, the enormous dose of 5 gm. borax mixed with 20 cc. water. The œsophageal probang was used. There was not the slightest trace of any intestinal symptom.

"Guinea pigs were fed with large doses (0.5 gm.) of borax. They were given this dose in 60 cc. water in their food every day for 95 days. The animals remained in their normal condition throughout the whole period, and at its close they had increased in weight. . . .

"The primary result of all these experiments is that no determined aversion of animals against borax and boric acid exists. This is so far favorable, as opposition to feeding on unfamiliar substances is not infrequently met with from the start. Moreover, the experiments demonstrate the important fact of increase of weight. . . . [The] figures suffice to justify the assumption that the increase in weight can not be due to chance factors. Cage feeding [as in the experiments] is more favorable to the gain of weight than feeding in the open, and therefore it would be a mistake to imagine that feeding with boracic preparations exercises a special influence on such increase. But certainly the conclusion is justified that nutrition was not impaired by the admixture of the said preparations. . . . The facts brought out by these feeding experiments are important because poisonous qualities have been attributed to borax and boric acid, whilst here we have the proof to the contrary."

A metabolism experiment was made with a dog fed borax. A period of 10 days, in which 20 gm. of borax was consumed daily in addition to the other food, was preceded and followed by periods under normal conditions. The average income and outgo of nitrogen in the 3 periods was as follows:

Metabolism experiment with a dog fed borax.

	Duration.	Nitrogen.			Loss.
		In food.	In urine.	In feces.	
	Days	*Grams.*	*Grams.*	*Grams.*	*Grams.*
Preliminary period (ration without borax)	10	8.75	6.46	2.30	0.01
Borax period (same ration with borax)	10	8.75	5.65	8.13	.03
After period (ration without borax)	10	8.75	6.21	2.57	.03

This experiment, in the author's opinion, indicates that boric acid hinders putrefaction in the intestines.

The influence of boric acid on salivary, gastric, and pancreatic digestion is discussed in connection with the author's experiments.

"Though the feeding experiments have not brought out any specially unfavorable influence on digestion where the maximum doses were not exceeded, it seemed desirable, nevertheless, to examine borax and boric acid in their relation to the process of digestion, in order to find out whether possibly they might do harm. . . . The results demonstrate that borax lowers the sugar-forming power. . . .

"[As shown by the tests] neither borax nor boric acid exercises any disturbing influence on the transformation of starch into sugar. In this respect they resemble saltpeter, whilst, on the other hand, even ½ per cent of carbonate of soda has a decidedly deleterious action."

A microscopic examination of the mucous membrane of a frog showed, in the author's opinion, that borax and boric acid can not be considered injurious to the ciliary epithelium.

The experiments with dogs are held to have shown that boric acid had no injurious effect upon the gastro-intestinal epithelium. Borax, however, had a more powerful action. A 2 per cent solution caused a distinct increase of mucous secretion and disintegration of epithelial cells, *i. e.*, a deleterious effect.

> "The intestinal effect is milder. Here, too, the cells become translucent, but only distinctly so when a 3 per cent solution is reached. There is no disintegration of epithelia under a 5 per cent solution. . . .
>
> "On the intestine the action of soda is considerably more powerful than that of borax. At 1 per cent solution the deleterious action commences, cells in large quantity being disintegrated, whereas a 1 per cent borax solution leaves the intestine intact. In the case of saltpeter, the injurious effect on the stomach—and on the intestinal membrane, too—begins at the ½ per cent solution. It is worthy of note that even common salt in a 5 per cent solution exercises an inflammatory action on the gastro-intestinal mucous membrane. Here, too, we have the proof that no other effect than an alkaline one can be ascribed to borax, and that it has no specific injurious action of its own.
>
> "For the practical purposes of alimentation such strong solutions of borax and boric acid do not come in question; but even if such should be taken, the intestinal contents would be so much diluted by the gastro-intestinal juice, by the flow of gastric juice, bile, and intestinal secretion, that the concentration would fall below the limit value. . . .
>
> "Animal experiments demonstrate further that borax is easily excreted from the system and that no accumulation takes place. . . .
>
> "Now, though severest criticism of medical observations and experience won from experimental research justify the conclusion that borax and boric acid are innocuous as preservatives of food, this assertion of course can only be valid within certain limits, a restriction which, however, applies to all victuals and drugs; for we know that medicines, admixtures to food, and even aliments, when taken injudiciously or in excess, cease to be wholesome, and suddenly become injurious substances. And, moreover, if harm could be done by borax and boric acid used in the preservation of food, the immense quantities which have already been swallowed would have aroused the attention of medical men, particularly as boracic preservation is openly practiced (as may be seen by the butchers' trade journals), and has been unreluctantly accepted by the working class.
>
> "For the preservation of meat boric acid is used in quantities of ½ to ¾ per cent; of this a great part is lost in watering the meat, particularly in the smoking process, for instance, so that we may estimate ¼ per cent as the maximum amount which reaches the system. Experience has proved that 1.2 gm. of boric acid or borax, if taken in food daily, even for a considerable time, does not affect health injuriously. Even quantities twice as large have not proved injurious, scientific investigations having decisively demonstrated that these doses are far below the limit where deleterious action commences."

The publication includes an extended bibliography of the subject.

Oat hay harvested at different stages of maturity, J. M. BARTLETT (*Maine Sta. Rpt. 1898, pp. 93-96*).—The author points out that oats are not an ideal crop for hay. To secure the best hay the oats should be dried quickly in bright sunlight. The composition of oats cut when in bloom (July 27), when nearly all the kernels were in the milk stage (August 25), and when nearly all the grain was in the dough stage (August 12), was determined. In the latter case the tops of the stalks were green, but the lower portions showed signs of ripening; therefore, the composition of each portion of the stalk was also determined. The yield of the first cutting was 4,418.8 lbs. of dry matter per acre; of the second cutting, 5,218.3 lbs., and of the third cutting, 4,571 lbs. The composition of the oat hay of the different cuttings follows:

Composition of oat hay of different cuttings. (*a*)

	Water.	Protein.	Fat.	Fiber.	Nitrogen-free extract.	Ash.
Oat hay:	*Per cent.*	*Per cent.*	*Per ct.*	*Per cent.*	*Per cent.*	*Per cent.*

a These values are taken from p. 76 of the Maine Sta. Rpt. 1898.

Digestion experiments with sheep, J. M. BARTLETT (*Maine Sta. Rpt. 1898, pp. 79–92*).—In continuation of previous work (E. S. R., 10, p. 879), a number of experiments with sheep were made by the usual methods to learn the digestibility and value of H. O. Horse Feed, flax meal, oat hay cut in bloom, cut when the grain was in milk, when the grain was in dough, when the grain was partly in bloom and partly in milk, and when the grain was partly in milk and partly in the dough stage.

Oat hay was fed with the flax meal, and the digestibility of the flax meal alone was calculated. Taking into account the fuel value of the food consumed, of the feces, and the fuel value of the urea excreted, the available fuel value of each ration was calculated.

The average results of the experiments follow:

Summary of digestion coefficients obtained in experiments with sheep.

	Dry matter.	Organic matter.	Protein	Fat.	Nitrogen-free extract.	Fiber.	Ash	Available energy of food.

An experiment in grazing a corn and cowpea field with steers, R. L. BENNETT (*Arkansas Sta. Bul. 58, pp. 97–100*).—The profit of grazing steers on a corn and cowpea field (after the corn was pulled), supplementing this with as much cotton seed as the animals require, was tested with 5 steers on a field of 5 acres. The corn yielded 25½ bu-to the acre, which was regarded as hardly an average crop. The cowpeas made more than an average growth of vines but less than an average crop of peas. None of the latter were picked.

The steers required 65 days to consume all the food on the 5 acres. They were allowed access to only one-third of the field at a time. The cotton seed was always accessible and was consumed *ad libitum*. During the first 30 days of the test, while the pea vines were yet green and peas were accessible, the steers ate very little cotton seed.

At the beginning of the test the 5 steers weighed 3,858 lbs. The average daily gain was 2 lbs. per steer. The average amount of cotton seed consumed per steer during the whole test was 250 lbs. Rating cotton seed at $6 per ton, and making suitable allowance for the cowpeas planted, the cultivation of the crop, and the labor of feeding the steers, the cost of a pound of gain was calculated to be 1.6 cts.

"In estimating the cost of the grazing, the cotton seed and cowpeas are charged to the feeding, but it is reasonable to suppose they will, as manure scattered over the soil, increase the yield of the succeeding crop more than their cost. The advantages of feeding cotton seed to the steers instead of corn are cheapness as a food and greater value as a fertilizer. It was estimated that the steers grazed the three lots of the field about as follows: [On the first plat, one third of the field,] all the pea vines, husks, fodder, and about one-fourth of the stalks were eaten. [On the second and third plats, each one-third of the field,] frost having fallen October 22, the steers ate about two-thirds of the pea vines, all the husks and fodder, but scarcely any of the stalks. The results of the grazing of this field indicate that the corn should be gathered and the animals turned to grazing as early as possible before frost."

Raising calves for profitable beef production, C. H. ELMENDORF (*Nebraska Sta. Press Bul. 11, pp. 8, figs. 2*).—The cost of raising calves dropped by 6 cows showing Shorthorn or Hereford blood was recorded. The cows cost $30 per head. All the calves were dropped after February 1, 1898. They were allowed to run with their dams from birth until the latter part of August. Two of them were then stabled and fed 6 lbs. of alfalfa hay and 1 lb. of a mixed grain ration consisting of ground oats and corn, bran, and oil meal, 4:4:1. The oats and corn were ground together in the proportion of 1:2. In the latter part of October all the calves were weaned and fed alfalfa with ground oats and corn, 1:2. The ration was gradually increased to 20 lbs of alfalfa and 4 lbs. of grain per head per day. The latter part of January, 1899, a pound of bran was added to the daily ration. The cows were fed 1 year and the calves until April 1, 1899. In discussing the financial returns, bran was rated at $9 and alfalfa at $3 per ton; oil meal at $1.45 per hundredweight; and corn and oats each at 25 cts. per bushel. The total cost of production, including keeping the cows, is estimated at $70.09. Making suitable allowance for cost of feed and interest on the value of the cows, the author calculates that there was a profit of $10.96 per head, the calves being worth $4.50 per hundred pounds.

"From statement of weights and gains it will be noted that the total gain for 160 days, October 22 to April 1, was 1,405 lbs., or an average daily gain of 1.46 lbs. per head per day. For the 95 days, October 22 to January 25, the gain was 745 lbs., or an average daily gain per head of practically 1.3 lbs., while for 65 days, January 25 to April 1, the gain was 660 lbs., or practically 1.7 lbs. per head per day. . . . The average daily feed ration for 160 days cost, say, 2.64 cts. per day, with compensating average gain of 1.46 lbs. per head per day, which, at $4.50 per cwt., would be worth 6.57 cts., practically a profit of 150 per cent on cost of feed consumed."

Experiments in pig feeding, C. W. BURKETT (*New Hampshire Sta. Bul. 66, pp. 111–122, dgms. 3*).—Tests were made of the comparative value for pigs of a number of feeding stuffs in combination with skim milk.

Pumpkins, cooked and uncooked; apples and pumpkins; corn meal and bran; corn meal (pp. 111–116).—These feeding stuffs were compared with 6 lots, each made up of 3 pigs. All the lots were fed skim milk. In addition lot 1 was fed corn meal and cooked pumpkins; lot 2, corn meal and raw pumpkins; lot 3, raw pumpkins; lot 4, corn meal; lot 5, cooked pumpkins and apples, 1:1; lot 6, corn meal and bran, 1:1. The pumpkins were raised at the station, at a cost of 40 cts. per ton. The apples were common cider apples or windfalls, valued at 10 cts. per bushel. Corn meal was rated at $16 and bran at $17 per ton and skim milk at 20 cts. per hundred pounds. The average results of the test, which covered 25 days, are shown in the following table:

Results of feeding pigs pumpkins, apples, corn meal, and bran with skim milk.

	Weight at beginning.	Average daily gain.	Feed consumed per pound of gain.				Cost per pound of gain.
			Milk	Grain.	Pumpkins.	Pumpkins and apples.	
	Pounds.	*Pounds.*	*Pounds*	*Pounds.*	*Pounds.*	*Pounds.*	*Cents.*
Lot 1 (skim milk, corn meal, cooked pumpkins)	416	2.21	3.79	3.09	4.47	....	3 32
Lot 2 (skim milk, corn meal, raw pumpkins)	426	2.26	3.70	3.02	7 93	....	3.31
Lot 3 (skim milk, raw pumpkins)	423	1.12	7.50	....	45.20	....	2.39
Lot 4 (skim milk corn meal)	418	1 97	4.92	3 77	....	....	3.81
Lot 5 (skim milk and cooked pumpkins and apples	420	1.54	5.45	....	....	32.40	4.64
Lot 6 (skim milk, corn meal, bran)	428	2 16	3.88	3.92	....	....	4.01

"Cooking pumpkins does not increase their feeding value. When pumpkins are available for pig feeding they can be fed most economically in connection with corn meal. While raw pumpkins fed in connection with skim milk produced a pound of gain at small cost, so few pounds were produced it is advisable to feed corn meal with them. Apples, even at the low price of 10 cts. per bushel, are not an economical food for pigs. Bran is not desirable as a food for pigs, even if fed with corn meal."

Feeding value of bran, fermented and unfermented; bran and corn meal; corn meal in pig feeding (pp. 116–120).—Since it is sometimes said that fermenting bran improves its feeding quality, the point was tested and the fermented and unfermented material compared with a mixture of bran and corn meal and bran alone, using 4 lots of 3 Chester White Berkshire pigs. The test covered 2 periods of 99 and 21 days. During the whole test all the lots were fed skim milk. In addition, lot 1 was fed fermented bran during the first period, lot 2 unfermented bran, lot

3 bran and corn meal, and lot 4 corn meal. During the second period all the lots were fed corn meal. "In fermenting the bran, it was steamed in a barrel and left for 10 days before it was used. By this time it was quite sour." The following table summarizes the results of the test, the financial statement being based on the same values as in the preceding test:

Comparative value of fermented and unfermented bran and corn meal for pigs.

	Weight at beginning.	Average daily gain.		Feed consumed per pound of gain, whole test.		Cost of food per pound of gain, whole period.
		First period.	Second period.	Grain.	Skim milk.	
	Pounds.	*Pounds*	*Pounds*	*Pounds*	*Pounds.*	*Cents.*
Lot 1 (fermented bran)	141	0.61	1.44	3.04	8.81	3.80
Lot 2 (unfermented bran)	144	.70	1.24	3.21	8.72	3,92
Lot 3 (bran and corn meal)	143	.76	.88	3.27	9.26	3.43
Lot 4 (corn meal)	141	1.08	1.38	2.84	6.89	3.32

"There is but little gained in fermenting bran for pig feeding. Bran is undesirable as a feeding stuff for pigs, fed either alone or in combination with corn meal."

Ear corn compared with ground corn and cob for pigs (pp. 120–122).—The economy of grinding corn was tested with 2 lots of 6 pigs each. Lot 1 was fed corn on the ear; lot 2, ground corn and cob, the same corn being used in each case. Both lots were also fed skim milk. Lot 1 weighed 152 lbs. at the beginning of the test, which covered 4 weeks, and lot 2, 148 lbs. The average daily gain of the 2 lots was 0.81 and 0.87 lb., respectively. Lot 1 required 8.92 lbs. of skim milk and 3.33 lbs. of grain; and lot 2, 8.55 lbs. of skim milk and 3.19 lbs. of grain per pound of gain.

Corn on the ear was rated at $16 per ton and the cost of grinding at 12 cts. per hundred pounds. In the author's opinion, the slightly better gains made on the ground material did not cover the cost of grinding.

Ground corn and cob has a slightly better feeding value than corn on the ear. For practical purposes it is more economical to feed corn on the ear rather than hauling to the mill and grinding for feed.

Experiments in pork production, J. H. GRISDALE (*Canada Cent. Expt. Farm Bul. 33, pp. 35, pl. 1, figs. 7*).—This bulletin summarizes the experiments in pig feeding conducted at the Central Experimental Farm from 1890 to the present time, the following general statements being drawn:

"It will not pay to cook feed for swine where economy of pork production is the sole consideration. There is a gradual increase in the quantity of feed consumed for every pound of gain in live weight after the average live weight exceeds 100 lbs. The most economical time to slaughter swine is when they weigh from 175 to 200 lbs. The greatest and most economical gains are made when the swine are able to eat the most feed in proportion to their weight.

"Frozen wheat may be used as a profitable feed for swine. Skim milk adds most materially to the value of a grain ration, and 100 lbs. mixed grains equal about 700 lbs. skim milk. The relative value of skim milk in any ration varies with the amount fed, the poorest returns per pound fed being obtained when the proportion of skim milk to the total food is the greatest. The average dressed weight of swine is about 76.44 per cent of the fasted weight.

"Skim milk is a most valuable adjunct to the grain ration when hard flesh is desired.

"Type of animals fed influences character of meat more than breed, *i. e.*, the fact of an animal being a Yorkshire or a Tamworth will not insure a good bacon carcass, but they must also be of a rangy type and fed in a certain way. Feeding mixed meal (barley, peas, and oats) with milk usually insures firm meat. The greatest gains from a given amount of grain appear to be made when it is ground and soaked for 24 hours. Part of the grain fed whole is frequently voided before being digested. Mixed grains are more economical than grains fed pure. Pigs whose rations are limited make, on the whole, more economical gains than pigs that are rushed. Maturity or ripeness of the animal affects the quality of the flesh."

The number of hens that can be profitably kept in one pen, G. M. GOWELL (*Maine Sta. Rpt. 1898, pp. 144–147*).—Records were kept of the number of eggs produced by 8 lots of Brahma pullets and 7 lots of Barred Plymouth Rock pullets. Four of these lots contained 15 pullets each; four, 20; four, 25; and three, 30. The several lots were kept in pens 10 by 16 ft. Each pen had the same amount of window surface. The roosts, gravel, bone, and water dishes and nests were arranged alike in all pens, and each had the same yard space. The test covered 6 months, beginning with November. The pullets in one of the lots were hatched April 16; all the others were hatched May 2. The profits were estimated on eggs at 2 cts. each and the food consumed per fowl at 50 cts. The average results of the test follow:

Average number of eggs and estimated net profit from hens in flocks of different sizes.

	Number of hens in each pen	Number of eggs produced per hen.	Number of eggs produced per pen	Value of eggs produced per pen	Value of food per pen	Income per pen less cost of food
Lots 1, 5, 9, and 13	*a* 15	65.1	976	$19.52	$7.50	$12.02
Lots 2, 6, 10 and 14	20	60.4	1,208	24.16	10.00	14.16
Lots 3, 7, 11, and 15	25	51.4	1,284	25.64	12.50	13.14
Lots 4, 8, and 12	30	40.1	1,203	24.06	15.00	9.06

a The April hatched hens in Pen 1 are not included in this table

"It will be observed that pens containing 20 birds did not give as much profit per bird as did pens of 15 birds, but the pens containing 20 birds gave a greater total net profit per pen than did those containing any greater or less number of birds. Pens with 25 birds gave slightly greater net returns than did the 15-bird pens. The pens that had 30 birds each gave very much less net returns than did any of the others. These tests show that when 20 birds were confined on 160 ft. of floor space they yielded more profit than did 15 birds when kept in a similar room. This is a matter of considerable consequence, for the cost of buildings, for the proper housing of birds during the cold winters of our climate is the greatest item of expense to which the poultryman is subjected."

A nest box for keeping individual egg records, G. M. GOWELL (*Maine Sta. Rpt. 1898, pp. 141–143, pl. 1, fig. 1*).—The author describes a nest box so arranged that the hen when entering the nest releases a door, which closes and fastens automatically. After laying, the hen is liberated by an attendant, and by numbering the egg to correspond with the number of the hen an accurate record may be kept of the egg production of individual hens. These nest boxes are being used in experiments undertaken with the object of breeding families which shall excel as egg producers.

Daily bread, DE MONTAIGNAC (*Le pain quotidien. Mont Luçon: Trillers, 1899; rev. in Jour. Hyg., 24 (1899), No. 1205, p. 348*).—The author discusses white bread and bread from different kinds of flour.

Shall bread be made in the home? FLORENCE R. FAXON (*New England Kitchen Mag., 12 (1899), No. 3, pp. 83-88*).—On the basis of statistics gathered in Quincy, Mass., the economy of home bread making is discussed. Methods of bread making are described, and the sanitary condition of the bakeries is also spoken of.

The advantages of cereals as food plants, F. L. SARGENT (*New England Kitchen Mag., 11 (1899), No. 6, pp. 219, 220*).—An extract from the author's book entitled "Corn Plants" (E. S. R., 11, p. 423).

Distilled water as a beverage (*New England Kitchen Mag., 11 (1899), No. 4, pp. 156, 157*).—The advantages and disadvantages of distilled water as a beverage are discussed.

Coffee and coffee substitutes, C. B. COCHRAN (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 548-557*).—An examination of 24 samples of ground coffee is reported, 19 of which were found to be adulterated. The adulterants were chicory or the roots of other plants showing similar microscopic structure, peas, pea skins, coffee hulls, wheat, or other cereals.

The substitutes for coffee (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 78-80*).—A brief report of the examination by C. B. Cochran of a number of samples of coffee substitutes.

Coffee and its adulterants (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 75-77*).—A general article quoting the Pennsylvania Pure Food law on the subject.

Chocolate and cocoa (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 90-92*).—The composition of cocoa beans is quoted and the manufacture and adulteration of chocolate discussed.

Cocoas and chocolates, C. B. COCHRAN (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 652-662*).—An examination of 41 samples of cocoas and chocolates is reported. The determinations include foreign starches, cane sugar, reducing sugar, fat, ash, acid equivalent of ash, and refraction number of fat.

Foods which protect others, O. FOLLOWELL (*Les aliments d'epargne. Paris: Jovet & Bayer, 1899; rev. in Jour. Hyg, 24 (1899), No. 1212, p. 404*).—Under this heading the author includes tea, coffee, kola, maté, etc. The use of these materials is discussed.

Beer, wine, and malt extracts (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 81-86*).—The examination of a number of samples of beers, wines, and malt extracts is reported.

Soda-water sirups, F. T. ASCHMAN (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 533-536*).—A number of samples of soda-water sirups were examined with a view to the detection of preservatives.

Mustard and its adulteration (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, p. 89*).—The article quotes the composition of mustard and gives brief directions for detecting its adulteration.

Pepper and its adulteration (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 89, 90*).—The composition of pepper is quoted and its principal adulterants noted.

The adulteration of foods, C. D. WOODS (*Rpt. Maine Bd. Agr. 1898, pp. 35-46*).—An address at the annual meeting of the Maine Board of Agriculture. Adulteration is defined, common methods of adulteration described, and the legislation on food adulteration of a number of States is cited.

Food adulteration in North Carolina, W. A. WITHERS (*North Carolina Sta. Spec. Bul. 53, pp. 19*).—A popular summary of bulletins of the station on the adulteration of vinegar, coffee and tea, baking powders, flour, and canned goods (E. S. R., 10, pp. 1077, 1089; 11, pp. 278, 960). The North Carolina legislation regarding food adulteration is noted.

Preliminary report on dietaries for hospitals for the insane, W. O. ATWATER (*New York State Lunacy Com. Rept. 1897–98, I, pp. 31–200*).—This article discusses food and its functions, dietaries with special reference to hospitals for the insane, and gives a number of tables showing the quantities of different food materials which are equal in nutritive value to a food chosen as a standard. On the basis of foods supplied, the nutrients in the daily dietary of 10 State hospitals for the insane were computed. From the statistics obtained, recommendations for modifying the diet were made.

The food value of alcohol, P. BJERRE (*Skand. Arch. Physiol., 9 (1899), No. 6, pp. 333–335*).—A number of experiments are reported in which alcohol formed part of the diet, and the conclusion is drawn that alcohol is a nutrient, since it supplies the body with energy and may take the place of other foods in the diet.

A new method of measuring the respired air and its oxygen content in experiments with man, U. SCHATERNIHON (*Physiologiste Russe, 1 (1899), No. 12–14, pp. 194–204, figs. 9, pl. 1*).—A comparatively simple apparatus is described of the type in which a sort of mask is worn over the nose and mouth.

Analyses of fodders and feeding stuffs, C. D. WOODS (*Maine Sta. Rpt. 1898, pp. 75–78*).—The composition of a number of fodders and feeding stuffs analyzed in connection with the station work is reported. The analyses included bran, corn meal, cotton-seed meal, Chicago gluten meal, king gluten meal, Blatchford's calf meal, Cleveland flax meal, linseed meal, Buffalo gluten feed, diamond gluten feed, gluten feed, mixed feed, Quaker oat feed, H. O. poultry feed, H. O. scratching feed for poultry, H. O. dairy feed, H. O. standard horse feed, H. O. horse feed, H. O. Scotch oat feed, H. O. "Victor" corn, oat, and barley chop, H. O. "De Fi" chop, H. O. oat bran, buckwheat middlings, wheat middlings, oat middlings, oat bran, oatena, ground oat hulls, grain hulls, corn germs, ground corn, oat hay (different cuttings and parts of stalk), corn silage, and hay.

Feeding-stuff inspection, C. D. WOODS (*Maine Sta. Rpt. 1898, pp. 48–60*).—This covers the same ground as two recent bulletins of the station (E. S. R., 10, pp. 381, 1089).

Feeding stuffs, J. A. VOELCKER (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), No. 4, pp. 661–663*).—This article reports the examination of linseed cake, cotton-seed cake, compound cakes, gluten refuse, and coffee husks.

The newer stock foods (*Rpt. Pennsylvania State Dept. Agr. 1898, pt. 1, pp. 70–72*).—Descriptions of gluten feed, Atlas meal, dried brewers' grains, malt sprouts, cerealine feed, hominy feed or chop, oat feed, and corn and oat chop.

The estimation of the products of peptic digestion, J. EFFRONT (*Chem. Ztg., 23 (1899), Nos. 75, pp. 770, 771; 76, pp. 783, 784*).—The determinations recommended include (1) total nitrogen, (2) total albuminoid nitrogen, (3) syntonine, (4) proteoses, and (5) peptones. Laboratory directions are given and methods are discussed.

Behavior and effect of sugars in the body, P. ALBERTONI (*Mem. Roy. Accad. Sci. Ist., Bologna, 5. ser., 8 (1899); Ann. Farm. e Chim., 1899, I, p. 245; Chem. Ztg., 23 (1899), No. 88, Repert., p. 316*).—Experiments with milk sugar and other sugars are reported. These were made on a dog by Hammerschlag's method.

The value of feeding standards to the practical farmer, C. D. WOODS (*Rpt. Maine Bd. Agr. 1898, pp. 161–178*).—An address (with discussion) delivered at the annual meeting of the Maine Board of Agriculture.

Straw vs. shavings as bedding for cattle and horses, E. H. HOWARD (*New York State Lunacy Com. Rpt. 1897–98, I, pp. 295, 296*).—On the basis of a test of one week's duration in a cow and horse stable at the Rochester State Hospital, the author concludes that under the local conditions straw is 40 per cent cheaper than shavings for bedding. A brief discussion of the report is given.

Stock feeding in its relation to the fertility of the farm, B. W. MCKEEN (*Rhode

Island State Bd. Agr. Rpt. 1898, pp. 238–250).—A popular article discussing the value of manure and urine of farm animals and the best methods of utilizing them.

The cattle industry of Colorado, Wyoming, and Nevada, and the sheep industry of Colorado in 1897, J. T. McNeely (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 377–381*).—A descriptive and statistical article.

The horse useful (*Kansas State Bd. Agr. Quart. Rpt. 1899, Dec. 31, pp. 1–180, pls. 21, figs. 18*).—The bulletin contains a number of articles on different breeds of horses, management and care of horses, feeding mares and colts, diseases of horses, etc.

The military administration of Germany and its relation to national horse breeding (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 372–376, pls. 5*).—This is a free translation of a recent publication of the German War Department describing the requirements for army horses. The conditions attending the use of brood mares from the Royal Cavalry Supply Depot at Karlsruhe for breeding are discussed.

Breeding zebras (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 369–371, pls. 2*).—A brief account is given of the experiments of Baron de Paraná of Brazil in crossing the zebra on a common mare.

Poultry division, A. A. Brigham (*Rhode Island Sta. Rpt. 1898, pp. 206–211*).—The author discusses some of the requirements for successful poultry raising which are often neglected, insists on the need of good ventilation and describes briefly an apparatus for insuring it.

Farm poultry (*Bul. North Carolina State Bd. Agr., 21 (1900), No. 2, pp. 32*).—A popular article describing various breeds of poultry, ducks, geese, and turkeys; the diseases of poultry, poultry houses, preserving eggs, etc.

The farmer's poultry, S. Cushman (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 177–190*).—As stated in the subtitle, this article contains suggestions as to housing, feeding, breeding, and marketing poultry.

DAIRY FARMING—DAIRYING.

Comparison of fall and spring calves and cows at Ultuna Agricultural College, 1861–1893, K. Oeberg (*Nord. Mejeri Tidn., 14 (1899), No. 30, p. 410*).—The author has compiled the data found on the records of the dairy herd at Ultuna Agricultural College (Sweden) to ascertain what difference, if any, exists between calves and cows dropped in the fall (October to January) and in the spring (March to June) as regards live weight, increase in weight, subsequent milk yields, longevity, etc. The records for calves extend from 1873 to 1880, inclusive, and those for cows from 1861 to 1893. Nothing is said as to the number of animals included in the compilation. [The dairy herd at Ultuna in 1896, at the visit of the writer, numbered 209 animals, of which 135 were milk cows, largely Ayrshires.—W.]

The average data are presented in the following table:

Comparison of calves and cows dropped in the fall and in the spring.

	Spring calves.	Fall calves.
Calves:	*Pounds.*	*Pounds.*
Average weight at birth	66.3	60.0
Weight at close of milk feeding (21 weeks)	296.4	306.7
Increase in live weight	230.1	246.7
Cows from spring and fall calves:		
Average live weight	1,102.0	1,102.0
Average yield of milk per year	4,628.0	4,786.6

While the data for a single year often differ considerably as to live weight, milk yield, and age, the average results for all the years are practically identical as regards the weight and age which the cows attained, while the cows dropped in the fall produced on the average 113 lbs. more milk per year per head than those dropped in the spring. The raising of fall calves is to be preferred, among other reasons, because such calves will be large enough to be put on pasture the following spring, and come in in the fall, producing the most milk at the time when it brings the highest price.—F. W. WOLL.

Effect of alcohol on the secretion of milk, R. ROSEMANN (*Arch. Phys. [Pflüger], 78 (1900), No. 9–10, pp. 466–504*).—The author reports 2 experiments with 2 cows. In the first experiment, which lasted a month, 96 per cent alcohol was added to the drinking water, giving 300 cc. of alcohol per head daily at first and gradually increasing the amount to 600 cc. The cow was perceptibly affected by the larger amounts of alcohol, appearing at times to be intoxicated. The yield and composition of the milk from the morning's and night's milkings of each day are given. In the second experiment only 300 cc. of alcohol per day was given as the maximum amount. The transmission of alcohol to the milk was studied especially in this period.

The author summarizes his results with the statements that (1) the feeding of alcohol had no effect on the secretion of the normal milk constituents; and (2) when given in moderate doses there was no transmission of alcohol to the milk, and when given in large doses only a very small amount of alcohol appeared in the milk, representing at the most from 0.2 to 0.6 per cent of the alcohol fed.

The literature of the subject is reviewed and discussed.

A contribution to the question of the source of milk fat, W. CASPARI (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, Sup. 1, pp. 267–280*).—This work is somewhat similar to that of Winternitz (E. S. R., 9, p. 690). A dog was used, and nitrogenous and carbonaceous rations were fed in different periods, with the addition of iodin fat. It was found on a meat diet that a not inconsiderable amount of the iodin fat of the food might be transmitted to the milk. In one case 23 per cent of the fat of the milk is calculated to have been derived directly from the food, which contained 63 per cent of its fat in the form of iodin fat. In the period immediately following, when no iodin fat was fed, from 4 to 8 per cent of the milk fat was found to be iodin fat, which must have been derived from the body supply. When carbohydrates predominated largely and iodin fat was added, the latter was found in the milk fat, up to 32 per cent. The author believes that although the fat of the body may be drawn upon for the production of milk fat, under like circumstances the organism gives the preference to the food fat.

The properties of asses' milk, ELLENBERGER (*Arch. Anat. u. Physiol., Physiol. Abt., 1899, No. 1–2, pp. 32–52*).—The article treats of the chemical and physical properties of asses' milk, its digestibility in artificial digestion trials, the composition of colostrum, and comparisons of asses' milk with human milk and cows' milk.

In a summary the author states that asses' milk is characterized by its singular chemical composition, especially its low fat content (usually about 1 per cent), its approximate agreement with human milk in albuminoids, its relatively high albumin content, with an entire absence of nucleo albumin, and its relatively larger content of milk sugar, averaging about 6 per cent. It is further characterized by a strongly alkaline reaction, a singular appearance, a peculiar odor and taste, its behavior toward acids, rennet, and pepsin, and by a frequent curdling on cooking. It is more easily digested than cows' milk, and in its digestion leaves no residue of nuclein or paranuclein. It agrees very well with children and adults and is well assimilated.

The effect of food on the hardness of butter and composition of butter fat, J. M. BARTLETT (*Maine Sta. Rpt. 1898, pp. 97–113*).—The author notes the work of a number of investigators on the effect of food on butter fat and reports experiments carried on during 3 winters, the primary object of which was to study the effect of gluten meals, varying greatly in fat content, on the texture of butter and the composition of butter fat. The data for the experiments are presented in tabular form and discussed and notes are given on methods of determining the hardness of butter.

The first experiment was made with 3 cows and covered 4 periods of 2 weeks each. Two gluten meals, one containing from 15 to 20 per cent of fat and the other from 7 to 10 per cent, were compared with cottonseed meal. The second experiment included 4 cows and extended over 5 periods of 3 weeks each, with transition periods of 1 week each. Flax meal was used in addition to the gluten meals in making up the different rations. In all the experiments the basal ration, consisting of hay and silage, was practically the same. The results of the 2 experiments indicated that the gluten rations containing large amounts of fat produced softer butter than those containing smaller amounts.

In the third experiment, made with 4 cows and covering 3 periods of 4 weeks each, the object was to determine whether it was the quality or the quantity of fat that affected the butter. The contrasted rations fed during the 3 periods contained an extracted gluten meal having a fat content of less than 3 per cent, tallow and extracted gluten meal, and the gluten meals used in the previous experiments. It was found that the butter was harder and the melting point of the butter fat higher during the period when tallow was added to the extracted gluten meal ration than during the period when the same ration was fed without the tallow. The author's conclusions follow:

"(1) The hardness of butter can be regulated to a large extent by the food of the cows.

"(2) Gluten products, such as gluten meal, feeds, etc., containing large percentages of oil produce soft butter and should not be fed to dairy cows used for butter production.

“(3) Gluten meals containing small percentages of fat, 3 per cent or less, and high percentages of protein, when fed in combination with corn meal and bran, will make butter sufficiently hard for this climate.

“(4) The glutens, however, if freed from fat will not produce butter of more than normal hardness and do not have the hardening effect of cotton-seed meals; when a very hard butter is desired some cotton-seed meal should be fed.”

The effect of feeding fat on the fat content of the milk, J. M. BARTLETT (*Maine Sta. Rpt. 1898, pp. 114–117*).—In the third experiment noted above the effect of the food upon the yield of butter fat was also studied. Owing to a partial loss of the records satisfactory conclusions could not be drawn. “The results are of interest, however, in showing the very decided increase in fat content of the milk for the first 2 weeks of the period when a ration rich in fat was fed, and also the decided drop in the third week.”

The content of volatile fatty acids in butter, P. VIETH (*Milch Ztg., 28 (1899), No. 50, pp. 785–787*).—The author reports investigations concerning the range in content of volatile fatty acids in butter, discusses the causes of variation, and reviews the work of other investigators.

A study was made of the butter fat from a herd of 60 cows. The herd was composed mainly of Shorthorns, but contained also some Kerry and Jersey cows. The Reichert number for the whole herd for 17 months ranged from 20.4 to 26.8, and for the different breeds for 3 months as follows: Shorthorn 21.4 to 25.9, Kerry 22.5 to 28.6, Jersey 20.3 to 27.2. The number for one Shorthorn cow 19 days after calving was 25.1. During the ninth and tenth months of lactation the number for another Shorthorn cow varied from 18.6 to 17.6, and for a third cow during the fourteenth and fifteenth months from 16.3 to 14.7.

Tests extending through one year were made of the butter from four private dairy herds. Herd 1 contained about 800 cows, with a daily milk production ranging throughout the year from 4,000 to 10,500 kg. Herd 2 contained about 1,200 cows, the daily yield of milk ranging from 5,000 to 14,000 kg. Herd 3 included about 2,500 cows, yielding from 5,000 kg. of milk per day in February to 24,000 in June. Herd 4 consisted of about 550 cows, producing daily from 2,000 to 8,000 kg. of milk. The methods of handling the different herds and the conditions affecting the work are described. Each herd was pastured without additional feed from May to October and stabled and fed during the remainder of the year. The larger number of the cows of herd 1 were fresh in February, herd 2 from October to March, herd 3 during the last half of March and the first half of April, and of herd 4 in April. The Reichert number for the different herds varied during the year as follows: Herd 1, 24.9 to 30.2; herd 2, 23.9 to 29.1; herd 3, 22.8 to 30.6; and herd 4, 22.8 to 31.3, averaging, respectively, 27.6, 27.2, 26.9, and 27.1. In general the Reichert number for the different herds was 28 or above from the first of February to the first of July and lowest during October. The results are held to show a connection between the decrease in the

volatile fatty acids of the butter and advance in the period of lactation, but furnish no conclusive evidence of the effect of other factors.

Report upon experimental exports of butter, 1897, H. E. ALVORD (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 83–136, pl. 1, figs. 6, dgm. 1*).—This is a report on experimental exports of selected creamery butter to British markets. The work was carried on by the Dairy Division of this Department, and included 9 shipments made from May to October, 1897, a full account of which is given. The butter exported was made at creameries in Connecticut, Iowa, Kansas, Massachusetts, Minnesota, New Hampshire, New York, Ohio, South Dakota, Vermont, and Wisconsin, and was prepared in practically the same manner as for home markets.

The author considers at some length the requirements of the London market, facilities for transportation on land and sea, time and cost of transportation, composition and quality of the butter exported as compared with that found in the London market, and profits from the trial shipments.

No satisfactory comparison of the butter exported by the Department and foreign butters by experts in London could be obtained. The general expressions of merchants, retail dealers, and consumers, extracts from which are given, "upon being merged in a 'composite' form, seem to place the best States butter as second to the Danish, Swedish, and best French, and no more than equal to the best Irish, Australian, and Canadian." The evidence, however, is considered conclusive that in nearly all cases the butter was retailed to consumers at the very highest prices paid for salted butter. As a business operation the results of the year are considered as reasonably satisfactory.

Appendixes to the report contain statistics on the exports of butter, imitation butter, and oleo oil from the United States; imports of butter into the United Kingdom; data in regard to the shipments made by the Department; an account of tests of the relative merits upon reaching the London market and the comparative keeping quality of butter as usually made and that made from pasteurized cream; the results of a trial in shipping unsalted butter; scoring and analyses of the butter exported and of foreign made butters; and a diagram showing the prices of butter in New York and London during 1897.

The results of the experiments in pasteurization are not considered by the author as conclusive, but as furnishing an instructive contribution to the subject. The work was done at Newton, Kans., by J. H. Monrad, whose conclusions follow:

"(1) Even for the home market, pasteurization will make some improvement in the butter of at least 75 creameries in every 100.

"(2) Fully as good 'body' can be obtained in butter made from pasteurized cream as from raw cream.

"(3) Heating cream even to 170° and hauling it 12 miles while hot is perfectly practicable, although the butter thus made did not show any higher scoring at the first trial as a result of this treatment.

"(4) With the proper arrangements the pasteurization of cream need not be much extra work aside from the cleaning of apparatus; but an extra man is needed if the preparing of starter and the care of the cream, as well as the extra cleaning, is to be given the proper attention.

"(5) A large supply of ice or a refrigerating machine is necessary in order to chill the cream sufficiently to get a good 'body.'

"(6) In ripening cream a lower acid seems better adapted to a very rich cream, and there are indications that a better flavor can be obtained from thin cream."

Two trials were made of exporting unsalted butter. The results were unsatisfactory on account of a portion of the butter becoming moldy and several accidents, but indicated the possibility of placing on the London market fresh roll butter made in the United States equaling in quality and condition that from the north of France, which brings the highest price in London.

Analyses numbering 35 in all were made at several experiment stations and at this Department of the different lots of butter exported, and 33 analyses were made of selected lots of the best butter to be found in London from 9 foreign sources. Analyses were also made by public analysts in London of the butter exported by the Department. The results, comparing the content of water and butter fat, are summarized in the following table:

Comparative composition of butter, United States and foreign.

Butter—where made and where analyzed.	Water.			Butter fat.		
	Lowest	Highest.	Average	Lowest	Highest.	Average.
United States	*Per cent*	*Per cent*	*Per cent*	*Per cent*	*Per cent*	*Per cent*
American analyses	8 12	12 87	10 85	84 21	89 49	86 84
London analyses	8 08	11 73	10 13	86 71	90.09	88 06
Foreign, United States analyses	8 62	15 50	12 40	78.50	89 27	84 57

Bacteria in butter and other milk products, WEISSENFELD (*Berlin. Klin. Wchnschr., 36 (1899), p. 1053; abs. in Chem. Ztg., 23 (1899), No. 98, Repert., p. 365*).—The author examined 32 samples of butter, partly from creamery and partly from peasant farms in the vicinity of Bonn, for tubercle bacilli, using the Obermüller method. Ten samples produced tuberculosis, but only 3 the true tuberculosis, the remainder being the pseudo form. Of the 22 samples of butter which gave negative results, 20 contained no pathogenic organisms, while one sample killed the animal by peritonitis and another, made from pasteurized milk, contained a rod bacillus which was not isolated.

Various albuminoid and casein preparations made from milk were examined with the result that some were found to contain large numbers of living bacteria.

Action of micro-organisms on butter fat, DUCLAUX (*Ind. Lait., 24 (1899), Nos. 42, pp. 333, 334; 43, pp. 341, 342*).—A sample of butter was melted and a portion of the fat decanted. The remaining portion of the sample was emulsified and subjected to the action of Penicillum. At the beginning of the experiment the fat contained 3.2 per cent butyric acid and 1.6 per cent caproic acid. At the end of 6 weeks the content of these two acids had decreased from 4.8 to 4.5 per cent. This diminution was found due to both evaporation and assimilation by the fungus. Three months later the content of volatile fatty acids estimated as butyric was 2.5 per cent. Nine months after the last determination the percentage of butyric acid was 1.16 and caproic acid 1.02, making a total of 2.18. The slight loss in volatile fatty acids during the last period is attributed to the feeble growth of the Penicillum. Butyrin was saponified by the fungus more easily than caproin and both of these more readily than the other glycerids.

It is noted that a sample of the butter used in the experiment exposed to the influence of the sun from November 15 to April 15 increased in weight 1.3 per cent and in content of volatile fatty acids from 4.80 to 5.48 per cent.

An investigation was made of the changes in the composition of cheese which had been kept in a damp cellar for 5 years. The water content of the cheese had increased from about 44 to 50.68 per cent. The residue from the ether extract, amounting to 28.31 per cent, was brown and viscous. A resinous substance was isolated from this residue and a preliminary study made of its properties. After deducting 5 per cent for the salt content there remained 16 01 per cent for the casein and nitrogenous substances. The fat content instead of being nearly equal to that of the casein, as in the fresh cheese, was from 1½ to 2 times as great. This proportion is considered in reality still greater, as fatty acids combined with the ammonia during the changes which had taken place in the cheese are estimated with the casein. Of the casein 5.48 per cent was found soluble in boiling water and 7.31 per cent soluble in strong alcohol. As compared with fresh cheese these figures are considered as showing the extensive changes that had taken place in the casein. Seventy-five per cent of the casein soluble in warm water and alcohol passed through a porcelain filter. The volatile fatty acids of the cheese, estimated as butyric, was about 0.05 per cent. The content of free ammonia was 0.5 per cent and of ammonia in combination with fatty acids 1.9 per cent.

Similar though less marked results were obtained in an examination of a cheese 8 months old. The water content was 36.26, fat 34.70, casein and nitrogenous substances 24.59, and salts 4.45 per cent.

The changes in the composition of the fat in the cheese are pointed out as intimately correlated with those taking place in the casein. By the action of the micro organisms ammonia is liberated from the casein, which renders the mass alkaline and causes a saponification of the fat. The fatty acids in turn neutralize the ammonia and permit the action of the germs to continue.

Bacteriological examinations for the dairy service, J. A. GILRUTH (*New Zealand Dept. Agr. Rpt. 1899, pp. 89—91*).—Water from a creamery at which there had been complaints of the butter was found to contain about 2,000 germs per cubic centimeter, composed of equal numbers of *Bacillus fluorescens nonliquefaciens* and what appeared to be *B. fluorescens liquefaciens*. The latter produced "a peculiar fetid odor" when grown on gelatin or bouillon, and this was found to be the case also when inoculated into tubes of butter, both when kept at room temperature and when placed in cold storage at about 45° F. Under the latter conditions the odor was discernible in 3 days. Keeping the organism in tubes of glycerine and of butter in a freezing chamber, maintained constantly below 32° F., did not interfere with its activity when thawed out.

"The above indicates how butter may possibly become contaminated with deleterious germs through the water used for washing, and that it would be possible for butter harboring such germs to be graded first-class here, yet, soon after arrival in London, to become uneatable."

A sample of well water from another creamery contained about 13,000 organisms per cubic centimeter, and the water from a stream flowing near the well, which probably supplied the latter in part, contained about 200,000 organisms. *Bacillus coli* was present in both samples. A sample of butter from the creamery contained as many as 64,000 organisms in what could be raised on the point of a fine platinum needle. The odor of the gelatin culture indicated the presence of a number of putrefactive bacteria, but no odor was detected when inoculated into sterilized butter.

Examinations of the water supply of several other factories are briefly mentioned as indicating the desirability of a system of filtration of the water supply.

The author examined a box of butter which had been frozen in New Zealand, sent to England, and returned in the freezing chamber. The number of bacteria present was estimated at from 6,000 to 8,000 per grain, the chief organisms being "staphylococci" and "red bacillus." Other samples of butter which had been frozen for various periods were found to contain as many as 10,000 organisms per grain.

"These results indicate the necessity there is in dairying for having utensils and water supply, all of which may be sources of contamination, as well as the milk, free from foreign bacteria."

Vitality and retention of virulence by certain pathogenic bacteria in milk and its products, O. F. DAWSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 224–228*).—Milk was inoculated with the bacteria of swine plague and then used for making butter. The virulence of the culture was determined at the beginning by inoculating a healthy rabbit, and inoculations were made at different stages in the process of butter making. The author concludes that "something (acid) is formed in the milk during the manufacture of butter by the ordinary method which is in 36 hours present in sufficient quantity to lessen the virulence of the swine plague bacterium, and that in 24 hours it is present in sufficient quantity to render this bacterium nonvirulent or to kill it entirely."

Similar experiments were made with the hog cholera bacillus, showing that "the hog cholera bacillus is more resistant than the swine plague bacteria. . . . Not until the fifth month does the organism begin to lose its virulence." The experiments also show that "hog cholera could be carried in sour milk and in butter, and that the organism remains virulent for at least 12 months in commercial butter."

Butter was infected with a virulent culture of tubercle bacilli and tested from time to time on guinea pigs. According to the results "the bacillus retains its virulence pretty uniformly for about 3 months, when it begins to attenuate. At the eighth month its virulence was considerably decreased."

A case is mentioned of an outbreak of tuberculosis in swine in which the source of infection was believed to have been traced to the refuse from a creamery upon which the pigs fed.

Chemical studies on the ripening of two kinds of brick cheese, O. LAXA (*Ztschr. Untersuch. Nahr. u. Genussmtl., 2 (1899), No. 11, pp. 851–859*).—These studies were on the Bohemian Harrach and Konopister cheeses. Analyses were made of the cheeses when fresh and at different stages of ripening, and special determinations were made of the different forms of nitrogenous compounds present, the individual ash constituents, and the physical constants. The author summarizes the results of his investigation as follows:

(1) The amount of water in the cheeses decreases through evaporation from the surface.

(2) The total solids decrease by decomposition of the sugar and the albuminoids.

(3) The milk sugar is completely decomposed by micro organisms, principally lactic-acid bacteria and yeasts.

(4) The lactic acid is in part broken up by micro-organisms, and in part changed by them to volatile acids.

(5) The casein is changed principally to caseogluten, less to amido compounds—ammonia and volatile fatty acids; the nitrogen is slightly diminished.

(6) The ash is diminished to a slight extent by mechanical means. The salt is transformed into soluble sodium phosphate, which by osmose is transferred to the surface and there separates insoluble calcium phosphate.

(7) There was no change in the amount of fat in the interior, or, if any, a decrease. On the surface, where the decomposition was greatest, there was an apparent relative increase, which is thought to be due to the extraction of nonfatty substances by the ether in the fat determination. The superficial fat was decomposed and the fatty acids set free, increasing the acid number.

The importance of lactic-acid ferments for the formation of albuminoid decomposition products in Emmenthaler cheese, together with some remarks on the ripening process, E. VON FREUDENREICH and O. JENSEN (*Landw. Jahrb. Schweiz, 13 (1899), pp.*

169–197; Milch Ztg., 28 (1899), Nos. 48, pp. 758–760; 49, pp. 773–775; 50, pp. 790, 791; 52, pp. 822–825).—The authors report experiments in making small experimental cheeses and cheeses of normal size from pasteurized milk inoculated with different forms of lactic-acid bacteria, Duclaux's tyrothrix bacilli, etc. Sixteen of the small cheeses were made. The results are interpreted to show that the ripened cheeses which had been inoculated with the lactic-acid bacteria contained more amid nitrogen than the control cheeses or those inoculated with tyrothrix bacilli. The latter contained the least of all. The cheese inoculated with lactic-acid bacteria had the taste of ripened cheese, while this was less marked in the other cheeses, or entirely absent. This fact is held to show that the decomposition products formed by the lactic-acid bacteria are the characteristic ones of ripened cheese.

The largest amount of soluble nitrogenous compounds was contained in the cheese which was not inoculated with micro-organisms of any kind. This, the authors believe, indicates that the change of the casein into soluble proteids is due, at least partially, to other causes than the lactic-acid bacteria, and that the principal mission of the latter is to further decompose the soluble proteids, although other experiments by the authors are held to show that lactic-acid bacteria are also able to produce soluble proteids.

The authors discuss the probable cause of the change in the casein in pasteurized and uninoculated cheese, mentioning liquefying bacteria and the ferment in milk discovered by Babcock and Russell. In regard to the possibility of the changes being due to liquefying bacteria, additional experiments showed that liquefying bacteria are not able to live in hard cheese, and rapidly decrease. This is especially the case when lactic-acid bacteria are present. Cheese made from pasteurized milk inoculated with spores of *Tyrothrix tenuis* (to eliminate the possible action of the enzym supposed to be formed by this micro-organism), and likewise uninoculated cheese, contained only the soluble and amid nitrogen, which was found in very fresh cheese. This is held to indicate that the natural enzym, which was destroyed by pasteurizing, plays a part in the process. The tyrothrix spores introduced into cheese did not develop, and no ripening took place. An experiment with lactic-acid bacteria (2 forms) inoculated into milk pasteurized at 90° C. "shows that the lactic-acid ferments can render the casein of cheese soluble without the aid of the natural milk enzym." From 4.26 to 5.26 per cent of the total nitrogen of the cheese (2 months old) was rendered soluble, and from ⅓ to about ¼ of these amounts was changed to amid nitrogen. [The authors' results show that in another similar experiment with cheese pasteurized at 90° and uninoculated, the cheese "contained very many *Bacillus schafferi*" when 2 months old, and that 4.98 per cent of the total nitrogen had been rendered soluble; furthermore, in another case cheese made from milk pasteurized at 85° C. for 5 minutes and not inoculated, contained *Bacillus acidi lactici* when 2 months old, and 4.06 per cent of the nitrogen had been rendered soluble.]

From this series of experiments with small experimental cheeses the authors draw the following conclusions:

(1) The liquefying bacteria, as *Tyrothrix tenuis* and *Bacillus I*, take absolutely no part in rendering soluble the casein of normal Emmenthaler cheese, which always contains large numbers of lactic-acid bacteria. The latter suppress the liquefying bacteria and hinder their development.

(2) Liquefying bacteria of the order of *Bacillus I* develop, at least in the earlier stages, in cheese made from pasteurized milk, in which the majority of the lactic-acid bacteria are killed or weakened, and render a part of the casein soluble. In such cheese the natural milk ferment of Babcock and Russell seems to play a part.

(3) The lactic-acid ferments can render the casein of cheese soluble without the aid of the natural milk enzym. For the present we are unable to determine how much of the solvent action on the casein in normal cheese is due to the action of the lactic-acid ferments and how much to the action of the natural milk enzym.

The reason given for the fact that the cheese made from pasteurized milk not inoculated with lactic-acid bacteria contained the largest amount of soluble nitrogen, is that such cheese did not become as acid as cheese containing the lactic-acid bacteria, and that the peptonizing action of both the lactic-acid bacteria and the natural milk enzym is weakened by the presence of acid.

Seven large cheeses were made in the creamery of the dairy school at Rütti by an expert cheese maker. In all cases the milk was pasteurized, remaining uninoculated in one case, and being inoculated with tyrothrix bacilli in one case and with laboratory cultures of lactic acid bacteria in three others. Rennet tablets were used in these 5 cases, and in the remaining 2 natural rennet was used, the milk not being inoculated. Considerable difficulty was experienced in making Emmenthaler cheese from pasteurized milk, the cheese lacking the proper consistency and porous condition.

The uninoculated cheese made with rennet tablets ripened least of all, although it was found to contain considerable numbers of lactic-acid bacteria. In time this cheese had the taste of ripened cheese. The tyrothrix bacilli imparted a bad taste to the cheese. The taste of the cheese inoculated with lactic-acid bacteria was that of ripened cheese, but it was not comparable with that of normal cheese. In general the results agreed with those obtained in the former series with experimental cheeses. The uninoculated cheese and that treated with tyrothrix contained less albuminoid nitrogen than that treated with lactic-acid bacteria, but the latter in turn contained less than the cheese made with natural rennet. The largest amount of soluble nitrogen was found in the cheese made with rennet tablets from uninoculated pasteurized milk.

Lecithin and traces of glycerin-phosphoric acid were found to be constituents of cheese, and in every case the lecithin decreased and the glycerin-phosphoric acid increased as the cheese ripened. It is suggested that the lecithin is gradually decomposed to glycerin-phosphoric acid, cholin, and higher fatty acids.

The following conclusions from the investigations are given:

(1) In the ripening of Emmenthaler cheese the so-called tyrothrix bacilli take no part. They do not multiply in normal cheese, and even when introduced in large numbers they have no effect on the formation of decomposition products. In general they have an injurious effect on the taste.

(2) The chief part in the ripening is taken by the lactic-acid bacteria, which multiply abundantly in cheese. These are capable of rendering the casein of cheese soluble and forming the decomposition products characteristic of ripe cheese.

(3) It is not improbable that the inherent milk enzym discovered by Babcock and Russell takes a part in ripening, by rendering the casein soluble and so lightening the work of the lactic-acid ferments.

(4) The pasteurizing of milk for Emmenthaler cheese unfavorably affects the quality of the cheese, and consequently is not applicable in practice.

(5) A loss of soluble cheese constituents during ripening has been confirmed, and lecithin and traces of glycerin-phosphoric acid have been recognized as new constituents of cheese.

Breeds of dairy cattle, H E. ALVORD (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 137–200, figs. 35*).—This deals with the origin and history, characteristics, milk and butter records, and types of the following breeds: Ayrshire, Brown Swiss, Devon, Dutch Belted, Guernsey, Holstein, Jersey, Normandy, Polled Durham, Red Poll, Shorthorn, and Simmenthaler. Illustrations are given of a bull and a cow of each breed. An appendix contains information relative to comparison of dairy breeds, points observed in judging dairy cattle, number of registered cattle in the United States, scale of points in use in the United States for judging different breeds of dairy cattle, and organizations of breeders of pure-bred cattle.

Breeds of dairy cattle, H. E. ALVORD (*U. S. Department of Agr., Farmers' Bul. 106, pp. 48, figs. 21*).—A reprint of the above, slightly revised and abridged.

The selection, breeding, and handling of the modern dairy cow to secure most profit, V. E. FULLER (*Rpt. Maine Bd. Agr. 1898, pp. 178–197*).—A popular discourse based largely on experience.

H. O. dairy feed for cows, T. WILDING (*New York State Lunacy Com. Rpt. 1897–98, 1, pp. 278, 279*).—The regular ration, consisting of 10 lbs. of middlings and 2 lbs. of linseed meal per cow daily, was compared with 12 lbs. of H. O. dairy feed, silage being fed with each ration. Three cows were used. The milk yield was very slightly larger on the H. O. feed, "but with the average cost of middlings and oil meal I feel satisfied that there is nothing to be gained in changing to the H. O. dairy feed."

Economical dairy foods, J. L. HILLS (*Rpt. Maine Bd. Agr. 1898, pp. 125–155*).—A popular discourse in which the respective values and economics of different classes of dairy foods are pointed out.

Herd records, G. M. GOWELL (*Maine Sta. Rpt. 1898, pp. 148–157*).—This is a monthly record of 24 cows for 1898, giving the yields of milk, fat, and butter from each cow. "Discussion of the data will not be undertaken until more results are secured and tabulated."

Milk, its properties and composition, M. KLIMMER (*Arch. Wiss. u. Prakt. Thierh., 26 (1900), No. 1, pp. 40–69*).—The author lays down the proposition that in the future milk control can not continue to be a purely chemical control, but in order to completely fulfill its mission it must be preeminently a veterinary control.

The article gives a brief review of the literature of milk, with a view to furnishing veterinarians with general information on the physical properties and chemical composition of milk, the variations in content of solids and fat, and the influence of various internal and external conditions on the composition. A bibliography of 148 titles is given.

Two further articles are promised on the adulteration of milk and its detection, and on milk hygiene.

Clarification of milk (*Hoard's Dairyman, 31 (1900), No. 5, p. 90*).—The term is applied to the process of removing impurities from milk by the use of a centrifugal separator so adjusted that the spouts empty into one vat where the skim milk and cream are mixed before bottling. The author notes the practical use made of the method and its advantages, and recommends that milk be clarified cold to lessen the loss of casein.

The occurrence of chromates as preservatives in milk, A. LEYS (*Jour. Pharm. et Chim., 6. ser., 10 (1899), pp. 337-340; abs. in Analyst, 25 (1900), Jan., p. 9*).—During the past year the author has often found chromates associated with formaldehyde, most frequently in the proportion of 1 part in 1,000 parts of milk, though considerably larger quantities have been used. Two tests for chromates are described.

Butter, W. A. WITHERS and J. M. PICKEL (*North Carolina Sta. Bul. 166, pp. 377-386*).—An introductory statement concerning the number and value of milch cows in the State is followed by a popular discussion of the chemical composition of animal fats, manufacture of oleomargarine, adulterants of butter and their detection, and adulteration of butter in North Carolina. Of 15 samples bought for butter in the open market and analyzed at the station one was found to be oleomargarine.

Butter export, C. L. MCKAY (*Western Creamery, 5 (1900), No. 6, pp. 13, 14*).—A brief discussion on the manufacture of butter for foreign markets.

Colored spots in cheese, R. A. PEARSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 229-234*).—A reprint of Circular 24 of the Bureau (E. S. R., 10, p. 593).

The home of Edam cheese, J. W. DECKER (*New York Produce Rev. and Amer. Creamery, 1900, Feb. 14, pp. 54-58, figs. 7*).—An illustrated description of the manufacture and sale of Edam cheese in Holland.

Fifty dairy rules (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 201-204*).—Reprinted from Farmers' Bulletin 63 (E. S. R., 9, p. 886).

The sanitary aspects of dairying, T. SMITH (*Rpt. Maine Bd. Agr. 1898, pp. 197-224*).—A popular article dealing with milk supply and sanitation, danger from tuberculosis, improvement of sanitary conditions of the dairy, etc.

Meat and milk inspection in Shanghai, W. J. BLACKWOOD (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 205-212*).

The so-called air churn, W. J. SPILLMAN (*Dairy Reporter, 3 (1900), No. 33, p. 526*).—Cautions farmers against the purchase of new and untested dairy apparatus.

VETERINARY SCIENCE AND PRACTICE.

Laboratory methods for the diagnosis of certain micro-organismal diseases, C. F. DAWSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 335-354, pls. 7*).—This paper presents details of methods for differential diagnoses of various diseases. Anthrax bacillus is readily stained blue with Loeffler's alkaline methylin blue. The organisms appear as rods with square ends, never blunt or round. In the case of malignant edema, the organism may be observed in chains, and the opposing ends are usually square, resembling in this respect the organism of anthrax. The terminal cell of the chain, however, is always rounded on the free end and never square. This differentiates the organism readily from that of anthrax.

The specific organism of rabies has never been isolated, but the most reliable of various methods adopted for diagnosis of rabies is that of subdural inoculation in rabbits. In the case of actinomycosis, if a small bit of a suspected tumor is crushed under a cover glass the organism, if present, will be seen as a mass of minute rays projecting from the center. The rays are club-shaped at the peripheral ends.

A brief description is given of a method for demonstrating the presence of Texas fever organism in the blood. This organism, being a protozoon called *Pyrosoma bigeminum*, has never been successfully cultivated upon nutrient media. In the diagnosis of tuberculosis, the author mentions the use of tuberculin and various stains for the tubercle bacillus. In the diagnosis of blackleg, it is to be remembered that this disease is not found in horses, adult cattle, or in swine. In anthrax the spleen is enlarged, but never in blackleg. The bacillus of blackleg is of about the same length and half as broad as that of malignant edema. The latter bacillus kills rabbits and guinea pigs, while the bacillus of blackleg is not known to be fatal to rabbits.

In tetanus the diagnosis usually depends upon clinical history. Death may occur in from 4 to 5 days. Difficulty in mastication and deglutition are early symptoms in the horse. The spine and legs become rigid, the tail being elevated and motionless. The muscular system becomes tetanic and a cold perspiration is often present. In the diagnosis of glanders the author mentions the use of mallein inoculations, and hypodermic injection of nasal discharge of suspected animals in guinea pigs. If the glanders organism is present in this material, in male guinea pigs acute orchitis is developed within from 48 to 72 hours. In making a differential diagnosis between swine plague and hog cholera, attention is called to the habit of the hog cholera bacillus to form clumps and to become agglutinated. This reaction is never noticed in the case of the organism of swine plague.

Chicken cholera should present little difficulty, from the fact that the germ is present in the blood in large numbers and the clinical symptoms are characteristic. In infectious leukæmia, a diagnosis can be readily reached by discovering the *Bacterium sanguinarium* in the feces of affected fowls. In tuberculosis of fowls, it should be remembered that the tubercles often appear as hard, horny, or soft and cheesy swellings on the skin and joints. In about 50 per cent of the cases the tubercles appear as round masses in the intestinal walls. Entero-hepatitis in turkeys may be readily diagnosed by finding *Amœba meleagridis*, which is the pathogenic organism of the disease.

In studying roup of fowls, the membranous patches in the mouth, throat, and nose should be ground up in a salt solution and injected hypodermically in small experimental animals. Nodular tæniasis may be differentiated from tuberculosis in fowls by the fact that in tuberculosis, lesions will be found also in the liver or other organs, while in nodular tæniasis no such lesions will be found except in the walls of the intestines.

A nodular disease of sheep, which has been mistaken for tuberculosis, may be readily recognized by the finding of the pathological agent, which is a nematode worm, *Œsophagostoma columbianum.*

The history of a tuberculous herd of cows, H. L. RUSSELL (*Wisconsin Sta. Bul. 78, pp. 16, figs. 7*).—An account is given of an outbreak of tuberculosis in a private herd, which had been improved by the purchase of some pure-bred animals, and of experiments made by the station on this herd in the application of Bang's weeding-out process. The first tuberculin test was made January 2, 1896. Thirteen out of 16 mature animals and 3 yearlings responded. Two showed physical symptoms of the disease and were slaughtered. A partition was constructed across the stable and the animals which had reacted were kept on one side, while the others were kept on the other side of this partition. The 2 sections of the herd were pastured in separate fields and watered out of different tanks. The stable was thoroughly disinfected.

On May 12 of the same year, another tuberculin test was applied, but no new cases of tuberculosis were indicated. Five calves, however, had been dropped in the meantime, 4 of them coming from the tuberculous section. These calves were separated at birth and fed on boiled milk. On April 26, 1897, a third test was applied. No new cases of tuberculosis had developed. All calves, whether from the tuberculous or nontuberculous section, were free from the disease. Two more old cows, in which the disease had progressed so as to become evident, were slaughtered. In 1898, only the young stock was tested, previous tuberculin tests having given uniform results. Two more of the original herd of tuberculous animals were killed. In February, 1899, a final test of the entire herd was made with the result that no new cases of the disease were found.

The history of the observations made upon this herd shows that the diseased animals became fewer and fewer as the more pronounced symptoms appeared, rendering the slaughter of the animals necessary; but not a single new case of the disease developed in any of the young animals. This is evidence that in this herd the disease was not inherited from the affected mother but could be contracted only after birth.

In connection with the tuberculin tests made upon this herd, it is of interest to note that none of the animals which originally reacted to tuberculin, failed to react during the subsequent tests.

The milk of this herd was frequently submitted for bacteriological examination and no tubercle bacilli were found. Calves from tuberculous mothers as well as nontuberculous mothers were allowed to suckle the reacting cows. Young cattle were also kept in contact with the affected herd in the stable and in the pasture, but in no case was the disease contracted. The author believes that the history of this herd demonstrates that a perfectly healthy herd can be built up from a tuberculous herd by this method. The results obtained would indicate that tuberculosis is not likely to be contracted from tuberculous animals until the disease has progressed so far that physical symptoms of the affection are apparent. Naturally it is impossible to say just when the milk of a tuberculous animal becomes dangerous and for this reason it is advisable always to pasteurize such milk.

The author suggests that when upon the application of the tuberculin test it is found that only a few of the herd are tuberculous, it would perhaps be advisable to slaughter these animals. When, on the other hand, more than a few or a large proportion of the herd reacts it would seem from an economic standpoint as well as from a sanitary standpoint to be inadvisable to destroy all of the reacting animals.

Tuberculosis and the station herd, F. L. RUSSELL (*Maine Sta. Rpt. 1898, pp. 136–140*).—When the tuberculin test was first applied to the college herd, a number of cows responded and all such animals were destroyed. The *post-mortem* examinations showed that certain cows had perhaps not yet become dangerous, but it was considered advisable to take strenuous measures for eradicating the disease. The barn, however, was full of hay and it was not thought possible to disinfect it. Cows were bought from the neighborhood to replace those which had been destroyed, and were subjected to the tuberculin test before placing them in the herd. During the following winter several additional cases of tuberculosis developed, and it was believed that these cases arose by infection from the stable. The stable was thoroughly disinfected, all movable objects being taken out, and walls and woodwork thoroughly sprayed with a solution of corrosive sublimate in proportion of 1 to 1,000 parts in water. Since this time no new cases of tuberculosis have developed, and it is believed that the herd is entirely free from this disease.

Some products of the tuberculosis bacillus and the treatment of experimental tuberculosis with antitoxic serum, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 305–317*).—This is a reprint from Transactions of the Association of American Physicians, 1897. A crystalline substance with a melting point of 161 to 164° C. was isolated from artificial liquid cultures of the tubercle bacillus. The substance was acid, and appeared to have nearly the same formula as teraconic acid. The crystals were dissolved in water and used for experimental inoculation of guinea pigs, the indications being that it was very active in causing necrosis of the tissue. Crystals dissolved in sterile water and injected into the liver produced, after 48 hours, a number of light spots in that organ. The substance possesses some immunizing power, a single injection of 0.002 gm. being sufficient to keep the animals alive some weeks longer than the cheeks. It has the effect of reducing the temperature in healthy and diseased animals.

It was found possible to isolate another substance from cultures of the tubercle bacillus which contained an albuminoid and which caused a temperature reaction. It is believed that the different reaction to tuberculin at different times is perhaps principally due to the antagonistic action of these two substances.

Experiments were conducted to determine the effect of the injection of attenuated tubercle bacillus. At first there was a slight decrease in weight and a local swelling. In about 8 weeks after the injection, the guinea pigs were apparently well and were inoculated with the virulent germ. The checks died within 6 weeks after inoculation, while vaccinated guinea pigs were in a healthy condition 4 months afterward.

Three cattle, of which one was tuberculous and the other two healthy, were given large doses of tuberculin and attenuated culture, the tuberculous animal receiving from November, 1894, to April, 1897, 19,407 cc. of tuberculin, and the 2 healthy animals receiving 11,425 and 18,100 cc. of attenuated culture, respectively. The serum from the cow which was treated with tuberculin caused a slight resistance to tuberculosis in guinea pigs, while the serum of the 2 cows which were treated with attenuated cultures produced a greater and more prolonged resistance on the part of experimental animals. Similar results were obtained by use of the serum from horses which had been treated with attenuated cultures.

The author concludes that the injection of the live culture of tubercle bacillus produces substances which are antitoxic to tuberculosis, and slightly antitoxic material is also produced by the injection of tuberculin in healthy animals.

The attenuated Bacillus tuberculosis: Its use in producing immunity from tuberculosis in guinea pigs, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 318–325*).—This is a reprint from the Medical News, December, 1894. Cultures of tubercle bacillus, which had been growing for several generations upon glycerine agar, were transferred to glycerine beef broth. After the fourteenth generation upon this culture medium, it was noticed that the germs were becoming attenuated and that the disease required 6 months for development.

Experiments were conducted to test the immunizing properties of attenuated cultures, from which the following results were obtained: Guinea pigs were apparently rendered immune to virulent cultures by repeated inoculation with an attenuated culture. A single injection of a small quantity of tuberculin seemed to increase the subsequent immunity produced by injection of the attenuated culture. Guinea pigs which were inoculated with the attenuated culture did not develop symptoms of tuberculosis, although under close observation for several months.

Texas fever, J. W. CONNAWAY and M. FRANCIS (*Missouri Sta. Bul. 48, pp. 66, figs. 11*).—The work on Texas fever which is recorded in this bulletin was carried out under the cooperation of the Missouri and Texas Experiment Stations and the Missouri State Board of Agriculture. The investigations involved the following three lines of work: (1) Experiments to determine whether sterile blood serum of immune cattle would produce immunity in other cattle; (2) experiments in immunizing cattle by tick infestation; (3) experiments in immunizing cattle by blood inoculation. The greater part of the bulletin is occupied with a report of experiments in blood inoculation. Experiments conducted with sterilized serum indicated that this substance is worthless for producing immunity in Northern cattle, and that the only way of producing immunity is by means of actual infection with the disease, either by tick infestation or by blood inoculation.

Twenty-one head of young cattle were infested with ticks, and of this number only one died from an acute attack of fever within the period of 12 to 20 days. The animal which died was a calf two months old, and was infested with an unusually large number of ticks. Later an acute fatal relapse took place in two other animals. The relapse occurred after a secondary infestation of ticks. These animals, however, were in bad condition and poorly nourished. It was concluded from these experiments in tick infestation that complete immunity can not be produced by a single infestation with the fever ticks. The immunizing process is a slow and gradual one, requiring several months or perhaps a year for its completion. The first infestation of ticks should be slight, and the subsequent infestations should not be made at too great intervals, provided that the animals endure the fever reaction which results from each infestation. It is advisable that calves be well nourished throughout the period of immunization, otherwise the growth of the calves may be stunted and fatal relapses will sometimes occur.

The authors conducted experiments in the production of immunity by blood inoculation on a large scale. From 1 to 2½ cc. of defibrinated blood was given hypodermically at each inoculation. The first dose of defibrinated blood was usually made smaller than the second or subsequent doses. The record of cases shows that inoculation fever begins about the eighth or ninth day after inoculation. This fever persists for from 7 to 8 days. Occasionally it may not be noticeable for more than 4 days, and sometimes it is prolonged to 15 days. The average daily temperature during the primary fever period is about 104½° F. Ordinarily a secondary-fever period occurred at about the twenty-fifth to the thirtieth day after inoculation, and continued for from 7 to 8 days. As a rule the secondary fever is not as severe as the first. Subsequent recurrences of fever are often noticed but are usually of a mild form.

Besides keeping a detailed record of changes in temperature of the experimental animals, the authors made records of the variation in red blood corpuscles by means of a hematocrit. In one lot, consisting of 6 head of animals, the average percentage of red blood corpuscles in the blood at the beginning of the experiment was 38.3. On the eighth day after inoculation the percentage had fallen to an average of 31.3. The destruction of blood corpuscles continued until on the fifteenth day of the experiment the percentage was 23.3. On the nineteenth day after inoculation, the temperatures were normal and the percentage of red blood corpuscles began slowly to increase.

During the inoculation fever certain physiological disturbances are noticed, among which may be mentioned a lack of relish of food, occasional bloating, disposition to eat dirt, muscular weakness, and trembling. In the lot of animals which was last mentioned, the hematocrit readings showed the lowest average percentage of red blood corpuscles on the thirty ninth day after inoculation. This occurred during the secondary fever period which began on the twenty-eighth day of the experiment. The lowest percentage of red blood corpuscles recorded on the thirty-ninth day was 14 per cent, and the highest 26 per cent, with an average of 21 per cent. In this same lot of animals a second inoculation was made on the seventy-seventh day of the experiment. The fever reaction was mild and there was only a slight destruction of red blood corpuscles. A third inoculation was made on the one hundred and thirty-second day of the experiment. The reaction from this inoculation was exceedingly slight. The first inoculation of this lot was made on January 7, 1899. The cattle were infested with the young ticks on May 5, 6, and 27. During June and July they carried fever ticks, but the ticks were not present on them in great numbers until August. On August 31 this experiment was closed, the temperature and average percentage of red blood corpuscles being normal at the time.

These experiments indicate that the diminution in red blood corpuscles corresponds closely in time to the rise of temperature, but it continues for a time after the temperature begins to fall. During the interval between the primary and secondary fever periods the percentage of red blood corpuscles rises, but falls again during the secondary-fever period. The authors conclude that "the recovery from the fever and the maintenance of an immune condition depend upon the ability of the animal (1) to keep in check the growth of the micro-parasites, (2) to supply new corpuscles as rapidly as they are destroyed, and (3) to remove waste products rapidly." Young animals withstand the inoculation fever far better than older ones. The most suitable age is from 8 to 12 months. Animals which are older than 12 months suffer severely from the inoculation fever and may die from a relapse, and if young calves are inoculated too soon after weaning, the digestive disturbances are apt to prove fatal in connection with the inoculation fever. Young calves may be safely inoculated, however, if allowed to remain with the cows.

The blood used in these experiments was taken from two sources, from naturally immune Southern cattle and Northern cattle made immune by tick infestation or blood inoculation. It was noticed that the virulence of the blood from different sources and from the same animal under different conditions may sometimes vary. It is, therefore, perhaps advisable to use blood from animals which have become thoroughly immune to the disease, since their blood will possess a more uniform virulence. The blood should be used when perfectly fresh. When blood for immunization is used from tick-infested animals, from 1 to 2½ cc. constitutes a sufficiently large dose.

The authors urge the advisability of maintaining a close watch upon the digestive functions of the animals during the period of immunization. It is necessary that the animals should be fed upon a highly nutritious diet, and it is desirable that the diet should be such as to maintain a lax condition of the bowels. Inoculation may be made at any season of the year, but in general it is advisable to choose seasons when the animals will not suffer from either too great cold or heat. Cattle may be safely inoculated in the South if they are kept free from ticks for about 60 days after inoculation, A few fatal relapses will occur, however, after the animal has become apparently immune, but these relapses may be prevented in large measure by careful feeding and by preventing unusual excitement of the inoculated animals. The process of immunization in Northern animals is probably such a gradual one that they should not be considered entirely immune until they have been kept one year in the South and subjected to tick infestation.

Inoculation to produce immunity from Texas fever in Northern cattle, E. C. SCHROEDER (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 273-288*).—The object of these experiments was to confirm the belief that a mild attack of Texas fever in Northern cattle would confer immunity against the disease. Each animal was given a hypodermic injection of blood drawn from the jugular vein of an immune Southern cow. The injections were made during the fall and winter and the cattle were exposed in the South during the following spring. The total number of animals which received injections was 11. Of this number, 9, together with 4 other cattle and 5 checks, were subsequently exposed to Texas fever in Virginia. Detailed records are given of the reaction and behavior of the cattle during the exposure. Of the 11 injected cattle 9 were exposed to Texas fever in permanently infected territory. One of the two older cattle which received an injection suffered a mild attack of Texas fever. The remaining animals which received injections escaped the disease entirely or suffered only a very mild form of the disease. Of the 5 check animals, 4 died, and the remaining one which survived suffered from a severe attack of Texas fever.

Blackleg in the United States and the distribution of vaccine by the Bureau of Animal Industry, V. A. NÖRGAARD (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 27-81, pl. 1, map 1, figs. 3*).—A preliminary report upon blackleg has already been noted (E. S. R., 10, p. 396). The detailed account which is given in the present paper is mainly based upon an outbreak of blackleg which occurred in Texas. During the 18 months covered by this report about 500,000 animals have been injected with vaccine sent out from the Bureau of Animal Industry, and loss from blackleg has been reduced to less than one-half per cent. A map is given which shows the distribution of blackleg in the United States and indicates the extent of the use of vaccine in different parts of the country.

The author states that blackleg vaccine may be manufactured for less than 1 cent per dose, and that the cost of production in the Bureau of Animal Industry does not exceed 1 cent per 10 doses. A detailed account is presented by way of historical review of our knowledge of blackleg. This disease occurs in nearly all the countries of the world. In the United States it is especially serious in Texas, Indian Territory, Oklahoma, Kansas, Nebraska, Colorado, North Dakota, and South Dakota.

The disease more frequently attacks animals between the ages of 6 and 18 months. Statistics collected in Switzerland indicate that 82 per cent of all cases occurred among cattle of ages varying from 6 months to 2 years. It has been claimed that the range cattle in Hungary are practically immune to blackleg. Similar claims have been made for the cattle of Algeria. In the United States it has been noticed that common range cattle are less susceptible than graded stock, and since it is probable that infection occurs by means of abrasions of the skin, it seems that in general thick skinned animals are less susceptible than more thin-skinned ones. Statistics do not indicate any striking difference in the susceptibility of the 2 sexes to blackleg, except perhaps among older animals, where it would appear that males are more susceptible. The spring and fall seasons are apparently most favorable for the development of the disease. Detailed accounts are given of the symptoms and of the pathological conditions to be found upon *post-mortem* examination.

The blackleg bacillus is described and an account is given of the biology of the organism and of the manner of its entrance into the body as already indicated.

Most cases of blackleg prove fatal. In reply to circulars, 120 stock owners out of 522 stated that they have seen animals recover from this disease, the number of reported recoveries amounting to 185. Since treatment is of little avail, the principal resource against this disease is prevention. Preventive measures may be classified as hygienic and prophylactic. Among the hygienic measures may be mentioned thorough disinfection of infected premises, and the careful burying or destruction of carcasses of animals dead of this disease. Some stock owners reported that blackleg never caused serious losses where it was possible to burn over the pastures regularly in the winter. The author discourages the use of seton or rowel in attempting to prevent an attack of blackleg.

An account is given of the different methods which have been proposed for the preparation of the preventive vaccine. At first 2 vaccinations were used, the first being with a mild and the second with a stronger virus. Later it was found possible to use a stronger virus at first and only one vaccination. In the Bureau of Animal Industry the finely ground and sifted blackleg meat is heated for 6 hours at a temperature of 93 or 94° F. This process was found to produce a virus of the desired strength. Detailed directions are given for the sterilization of injection apparatus and the preparation and use of the vaccine.

The diagnosis of glanders, V. M. SULIN (*Arch. Vet. Nauk, St. Petersburg, 29 (1899), No. 9, pp. 454–473*).—A number of experimental inoculations of mallein were made both with healthy and glanderous horses. The object of the experiments was to determine the variation in the number of white blood corpuscles under the influence of mallein. The results of this investigation may be stated as follows: The leucocytes possess a greater significance in the young than in adult horses, and the least significance in old horses. In healthy horses the fluctuation in the number of leucocytes is insignificant. A much greater fluctuation is to be observed in glanderous horses. In healthy horses the number of leucocytes undergoes no change after injection with mallein, or, if a variation is observed, it has no connection with the action of the mallein. In glanderous horses, after the mallein injection, there is always a greater or less decrease in the number of leucocytes. This process is observed most frequently about 6 hours after the injection, and more often earlier than later. Following this process there is always an increase in the number of leucocytes. Both of these processes take place even in case of an already existing leucocytosis. The appearance of leucocytosis is not synchronous with the elevation of temperature, but may be either earlier or later. Leucocytosis and aleucocytosis occur also in such glanderous horses as do not react to the mallein by a rise in temperature. The author also investigated the question of the relationship of the different kinds of leucocytes to one another and of the relative fluctuation of their numbers under the influence of mallein.

Heart-water experiments, R. W. DIXON (*Agr. Jour. Cape Good Hope, 15 (1899), No. 12, pp. 790–792*).—Heart water is a contagious disease of sheep and goats which is probably carried from animal to animal by means of the ticks. The author undertook a number of experiments in inoculation of sheep and goats for the purpose of producing immunity against the disease. The method of inoculation was with defibrinated virulent blood. The length of immunity conferred by this method was from 1 to 2 months. The author recommends that stringent methods be adopted for the destruction of the ticks, and suggests that by repeated spraying with paraffin and solution of arsenic or some other similar insecticide, the number of the ticks might be so reduced as to materially diminish the prevalence of heart water among sheep.

Notes on roup in fowls, J. BARLOW (*Rhode Island Sta. Rpt. 1898, pp. 97–105*).—In this article the author gives a general description of the symptoms of the disease in fowls, with a discussion of the literature bearing upon the subject. It is stated that in certain parts of the State the disease causes large losses to poultry raisers every year. Consideration is given to the question of the relationship between roup of fowls and diphtheria of human beings, and also of the question of the contagiousness of roup. Instances are cited from the literature of roup in which the disease seemed to be transmitted from fowls to man and from man to fowls. In order to determine the method of contagion, experiments were made in applying portions of the discharge from diseased fowls to the eyes of healthy fowls. After 10 days the disease was manifested. Healthy fowls were also shut up with diseased ones and made to eat and drink from the same receptacles. In these cases also the healthy fowls soon acquired the disease.

In the treatment of roup the author insists upon the importance of immediately isolating all diseased poultry, and believes that fowls which have once had the disease should not be afterwards used for breeding. The diseased fowls should be placed in comfortable quarters and should receive plenty of food. The exudate of membranous material formed in the throat or nostrils may be removed, and antiseptic washes, such as dilute carbolic acid, a 1 to 2,000 solution of corrosive sublimate, and peroxid of hydrogen in 3 per cent aqueous solution may be used with good results.

Asthenia (going light) in fowls, C. F. DAWSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 329–333, pl. 1*).—An outbreak of a fowl disease having occurred in Hyattsville, Md., a few fowls were brought to the Bureau of Animal Industry for investigation The disease was a chronic one, lasting about 3 months before a fatal issue. Upon making *post-mortem* examination, it was found that the duodenum was the only organ which was noticeably affected, the lining of this part of the intestine showing a catarrhal condition. Cultures were made from the contents of the duodenum with the result that a single species of bacterium was found. Hypodermic inoculations of pure cultures of this organism in a guinea pig produced death within 24 hours. A *post-mortem* examination of the guinea pig revealed the presence of the germ in lesions of the liver, spleen, and lungs. A description is given of the organism under the name of *Bacterium astheniæ*, and an account is presented of the behavior of the organism upon various culture media. This organism has the power of vegitating within wide temperature limits, from 50 to 120° F. A freezing temperature for 24 hours did not kill it. Two weeks' drying in diffused sunlight was not fatal to it.

As treatment for this disease of fowls, the author recommends purgation with castor oil in two-teaspoonful doses or calomel in repeated $\frac{1}{4}$-grain doses; purgation to be followed with tonic treatment.

The rôle of insects, Arachnids and Myriapoda, as carriers of human and animal diseases which are produced by bacteria and animal parasites, G. H. F. NUTTALL (*Hyg. Rundschau, 9 (1899), Nos. 5, pp. 209–220; 6, pp. 275–289; 8, pp. 393–408; 10, pp. 503–520; 12, pp. 606–620*).—In this series of articles the author presents an elaborate digest of the literature of the subject in connection with a bibliography of nearly 300 titles. Among the numerous special subjects treated in these articles, we may mention the following: The transmission of anthrax by flies (Tabanus, Hæmatopota, Musca, Stomoxys, etc.), beetles and Cimex and Pulex; the transmission by various insects of the organisms of hog cholera, chicken cholera, erysipelas, recurrent fever, yellow fever, and typhus; the transmission of tuberculosis by *Musca domestica* and *Acanthia lectularia;* the agency of various species of Ixodes in carrying contagious diseases; the transmission of contagious diseases by *Sarcopsylla penetrans,* species of Trombididæ, and various round and flat worms; and a discussion of the relationship of the cattle tick to the transmission of Texas fever.

Report of the State veterinarian, L. PEARSON (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 151–187*).—A report of work on the following diseases: Rabies, anthrax, cornstalk disease, hog cholera, tuberculosis, glanders, blackleg, abortion, milk fever, Texas fever, lungworm disease, cowpox, and dysentery of calves.

Report of the veterinary division, J. A. GILRUTH (*New Zealand Dept. Agr. Rpt. 1899, pp. 60–91, pls. 9*) —This report presents an account of a supposed outbreak of contagious pleuro-pneumonia, of the prevalence, spread, and methods of control and extermination of tuberculosis, with reports on tuberculin tests, actinomycosis, parasitic gastritis in calves, red water, milk fever, cirrhosis of the liver, and bacteriological examinations for the dairy service.

Report of government veterinarian, A. PARK (*New Zealand Dept. Agr. Rpt. 1899, pp. 115–122*).—This report contains an account of a large number of tuberculin tests, with an account of the *post-mortem* findings in condemned animals.

Report of government veterinarian, C. J. REAKES (*New Zealand Dept. Agr. Rpt. 1899, pp. 122–132, pl. 1*).—The author presents notes on the "Winton" disease of horses, actinomycosis, milk fever, tuberculosis of cattle and of pigs, and swine fever.

Contagious diseases of animals in European countries (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 428–439*).—A statistical account of the prevalence in the various European countries of contagious pleuro-pneumonia, foot-and-mouth disease, swine fever, rabies, glanders, sheep pox, scab, hog cholera, blackleg, anthrax, etc.

The reaction of the lymphatic glands to micro-organisms, G. PEREZ (*Ann. Ig. Sper., n. ser., 8 (1898), No. 1, pp. 1–103*).—An elaborate series of experiments with inoculations of pathogenic organisms in dogs, guinea pigs, and rabbits.

Influence of the lymphatic glands in the production of immunity, L. MANFREDI and P. VIOLA (*Ann. Ig. Sper., n. ser., 8 (1898), No. 4, pp. 456–489*).—The lymphatic system is endowed with a high resisting power against anthrax, typhus, and diphtheria, and plays an important rôle in immunization.

Lupines as plants poisonous to stock, E. V. WILCOX (*Jour. Comp. Med. and Vet. Arch., 20 (1899), No. 13, pp. 766–774*).—A brief discussion of cases of stock poisoning from lupins, with a bibliography.

Studies on anthrax, O. CASAGRANDI (*Ann. Ig. Sper., 9 (1899), No. 2, pp. 212–234*).

Actinomycosis, J. B. WRIGHT (*Jour. Comp. Med. and Vet. Arch., 20 (1899), No. 12, pp. 758–763*).—A discussion of the pathological anatomy of the disease in cattle, swine, sheep, and horses, with mention of the iodid of potash treatment and preventive measures.

The excretion of tetanus virus by the kidneys, S. J. GOLDBERG (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 18–19, pp. 547, 548*).—The author conducted experimental investigations upon rabbits and guinea pigs. It was found, as a result of these experiments, that tetanus virus was not present either in the excretion from the kidneys or in the amniotic water of these animals.

The composition of the tuberculosis and glanders bacilli, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 295–300*).—Reprinted from the American Chemical Journal for August, 1895. The elementary and proximate composition are given, and the data discussed in comparison with the work of others.

Notes upon the fats contained in the tuberculosis bacilli, E. A. DE SCHWEINITZ and M. DORSET (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 301, 302*).—Reprinted from the Journal of the American Chemical Society for May, 1896 (E. S. R., 8, p. 104).

The mineral constituents of the tubercle bacilli, E. A. DE SCHWEINITZ and M. DORSET (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 302–304, pls. 2*).—Reprinted from the Journal of the American Chemical Society (E. S. R., 10, p. 1016).

A new stain for Bacillus tuberculosis, M. DORSET (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 326–328*).—Since the tubercle bacillus has been shown to contain about 40 per cent of material which is soluble in ether, it was decided to try Sudan III as a stain, this stain being especially recommended for fatty material. Cover glass preparations were made and then immersed for 5 minutes in a saturated solution of Sudan III in 80 per cent alcohol. This stain gave excellent results. The same stain used in pure cultures of hog cholera, glanders, typhoid, anthrax, symptomatic anthrax, diphtheria, and other organisms gave negative results. Sudan III is therefore considered a differential stain for the tubercle bacillus.

The relation of the farmer to bovine tuberculosis, V. I. SPEAR (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 191–202*).—A popular discussion of the practical value of the tuberculin test and of means to be adopted in freeing herds from tuberculosis and preventing their reinfection.

Combating tuberculosis of man and animals in France and other countries, L. H. PETTIT and E. LECLAINCHE (*Rev. Tuberculose, Paris, 7 (1899), No. 4, pp. 355–373*).—Notes on the methods adopted in various countries in the reduction of tuberculosis.

Tuberculosis and how to eradicate it, J. M. CARTER (*Pennsylvania Dept. Agr. Rpt. 1898, pt. 1, pp. 340–346*).—A brief account of the distribution of tuberculosis which followed upon the breaking up and sale of a tuberculous herd.

Prevention of bovine tuberculosis, L. STUBBE (*Jour. Soc. Cent. Agr. Belg., 47 (1899), No. 2, pp. 61–66*).—Recommends the slaughter of animals with clinical symptoms of tuberculosis and of those which react to tuberculin, and the payment of an indemnity for such animals.

Experiments with the antitubercular serum of Maragliano, S. CRESCIMANNO (*Sieroterapia, 2 (1898), No. 11, pp. 126–128*).—This serum has curative action but does not protect the organism against subsequent infection by tuberculosis. The serum has no injurious effects upon the organism into which it is injected.

Some results in the treatment of tuberculosis with antituberculosis serum, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 289–295*).—This article records the results of experiments upon human tuberculous patients with an antituberculosis serum prepared by the Bureau of Animal Industry. Of the 34 patients who were treated, 16 were in the incipient stage, 15 were moderately advanced, and 3 were far advanced. The physical signs, expectoration, temperature, cough, appetite, and weight were improved in the majority of cases. The experimental work thus far done on guinea pigs, and the results obtained by the use of the antituberculosis serum on man indicate that this serum obtained from horses possesses considerable value.

The cattle tick and tuberculosis in New South Wales, G. S. BAKER (*U. S. Dept. Agr. Bureau of Animal Industry Rpt. 1898, p. 386*).—A brief note on the great prevalence of the cattle tick in New South Wales and on the frequency with which tuberculous animals are used for meat.

A cattle disease in Marshall County, Kansas (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 382–384*).—An outbreak of a disease which occurred at Blue Rapids, Kans., was investigated by R. P. Steddom. The disease is characterized as being essentially an inflammation of the external genital organs. The application of silver nitrate and a 5 per cent solution of creolin is reported as giving good results.

A cattle disease in Uruguay, A. W. SWALM (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, p. 385*).—A brief note on veterinary regulations in Uruguay concerning Texas fever.

Cattle quarantine line, C. CURTICE (*North Carolina Sta. Spec. Bul. 52, pp. 28*).—This bulletin contains a copy of Order No. 24 of the Bureau of Animal Industry of this Department regarding cattle transportation, a statement of the North Carolina State laws regarding traffic in cattle, a proclamation of quarantine by the governor of North Carolina, a special order of the Secretary of Agriculture modifying quarantine line for the State, quotations from newspapers regarding cattle quarantine, a copy of the Virginia State law concerning cattle transportation, and a copy of an act to prevent the spread of cattle distemper or tick fever and other contagious or infectious diseases of live stock, which latter has been brought before the general assembly of North Carolina.

Concerning a disease of sheep, F. MERCANTI and S. DESSY (*Ann. Ig. Sper., n. ser., 8 (1898), No. 4, pp. 381–395*).—A study of the effects of toxic substances produced by intestinal worms in sheep.

Distomatosis, S. LYUDSKANOV (*Vet. Sbirka, 7 (1898), No. 4–5, pp. 73–86*).—Notes on *Distoma hepaticum* and *D. lanceolatum*, with an account of the symptoms, course, and prevention of the disease caused by their presence in sheep.

Experiments with lime and sulphur dip, A. G. DAVISON (*Agr. Jour. Cape Good Hope, 15 (1899), No. 13, pp. 843–845*).—It was found that the wool of Tasmanian sheep was not injured by this dip.

Feeding wild plants to sheep, S. B NELSON (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 421–425*).—This paper is reprinted from Bulletin 22 of the Bureau (E. S. R., 10, p. 793).

Swine fever, J. A. GILRUTH (*New Zealand Dept. Agr. Rpt. 1899, pp. 92–115, pls. 3*).—A detailed account is given of outbreaks of this disease in different parts of New Zealand. The disease is considered the same as that known as hog cholera in this country. Numerous cultures were made of the specific organisms and a number of inoculation experiments were carried on with guinea pigs, rabbits, pigeons, and pigs. In these cases careful *post-mortem* examinations were made and the pathological conditions were observed and described in detail. It was found that in this disease pulmonary and pleural lesions may and frequently do occur independently of the characteristic bowel complications of swine fever. The author believes that it is doubtful whether hog cholera and swine plague will prove to be distinct diseases.

The production of immunity in guinea pigs from hog cholera by the use of blood serum from immunified animals, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 269–272*).—Reprint of a paper read before the American Association for the Advancement of Science, in 1892.

Enzyms, or soluble ferments, of the hog cholera germ, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 266–268*).—Reprint of an article read at the American Association for the Advancement of Science, in 1892.

The serum treatment for swine plague and hog cholera, E. A. DE SCHWEINITZ (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 235–248, pls. 2*).—This report is essentially the same as that contained in Bulletin 23 of the Bureau (E. S. R., 11, pp. 89, 90).

Experiments in stamping out hog cholera in Page County, Iowa (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 249–265*).—This is a statistical account of the work done on hog cholera in Iowa (E. S. R., 11, pp. 89, 90).

Partial paralysis and crippling of swine, J. H. REED and G. E. DAY (*Rpt. Agr., New Brunswick, 1899, pp. 310–315*).—Notes on the symptoms and treatment of this disease.

The germicide value of acrolein, E. KOCH and G. FUCHS (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 18-19, pp. 560-563*).—Acrolein in its chemical constitution is distinctly related to formalin. In the experiments which were undertaken by the author, this substance was found to be even more effective than formalin in destroying bacteria.

A new method for the disinfection of stalls, R. WALTHER and A. SCHLOSSMANN (*Ztschr. Tiermed., 2 (1898), No. 4, pp. 269-279, fig. 1*).—An apparatus was employed which filled the stall with a mist of glycoformal, which is composed of 60 parts of water, 30 parts of formol, and 10 parts of glycerine.

Disinfection, E. A. A. GRANGE (*Jour. Comp. Med. and Vet. Arch., 20 (1899), No. 11, pp. 674-680*).—A discussion of the value of various substances for this purpose.

Stable disinfection, J. B. PAIGE (*Rhode Island State Bd. Agr. Rpt. 1898, pp. 213-222*).—The author discusses the natural and artificial remedies which are to be relied upon for disinfecting stables. The disinfectant agencies which are discussed are sunlight, dry and moist heat, carbolic acid, creolin, lysol, disinfektol, corrosive sublimate, sulphur dioxid, and chlorin gas.

Contribution to a study of the disinfecting power of common soap, A. SERAFINI (*Ann. Ig. Sper., n. ser., 8 (1898), No. 2, pp. 199-221*).—Both soda and potash soaps possess considerable antiseptic power. A bibliography of the literature of this question is added to the article.

Cooperation between the experiment station veterinarian and the local veterinarian, A. W. BITTING (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 426, 427*).—This is a reprint from Bulletin 22 of this Bureau (E. S. R., 10, p. 793).

STATISTICS—MISCELLANEOUS.

Fourteenth Annual Report of Maine Station, 1898 (*Maine Sta. Rpt. 1898, pp. 242*).—This contains the organization list of the station; a brief report by the director; list of acknowledgments; reprints of Bulletin 41, Dehorning cows (E. S. R., 10, p. 395), and Bulletin 42, Ornamenting home grounds (E. S. R., 10, p. 355); abstracts of Bulletins 43-45; reprints of Bulletin 46, Some ornamental plants for Maine (E. S. R., 10, p. 855), and Bulletin 47, Wheat offals sold in Maine in 1898 (E. S. R., 10, p. 1089); miscellaneous articles noted elsewhere; and a report of the treasurer for the fiscal year ended June 30, 1898.

Eleventh Annual Report of Rhode Island Station, 1898 (*Rhode Island Sta. Rpt. 1898, pp. 75-240*).—This includes the organization list of the station; a report of the director giving a summary account of the principal lines of investigational work carried on during the year, with notes on the staff, equipment, and publications of the station; departmental reports containing a number of articles abstracted elsewhere; lists of donations, exchanges, and the publications of the station since 1888; and an index to the report and Bulletins 47-51 issued during the year. The financial statement for the fiscal year ended June 30, 1898, is given in the report of the college, p. 90.

Eighth Annual Report of Washington Station, 1898 (*Washington Sta. Rpt. 1898, pp. 8*).—This contains the organization list, a brief report by the director reviewing the station work for the year, and a financial statement for the fiscal year ended June 30, 1898.

Fifteenth Annual Report of the Bureau of Animal Industry, 1898 (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 647, pls. 26, figs. 69*).—This contains the report of the chief of the Bureau, a number of articles noted elsewhere, abstracts of some 20 station bulletins reporting investigations along lines embraced in animal industry, and extracts from consular reports and from correspondents. The report also contains statistics of the movement of farm animals, range or average price of farm animals at Chicago for 1897 and 1898, imports and exports of animals and animal products and the number and value of farm animals for the same years. A list of State live stock sanitary boards, secretaries of State boards of health, and State [illegible] having control of contagious and infectious diseases among domestic animals is given, and the rules and regulations of the Bureau issued in 1897 and 1898 are quoted.

Experiment Station Work—XIII (*U. S. Dept. Agr., Farmers' Bul. 107, pp. 32, figs. 2*).—This number contains articles on the following subjects: Fertilizer requirements of crops, persimmons, forcing rhubarb, grinding corn for cows, waste in feeding cornstalks, molasses for farm animals, feeding ducks, cost of raising calves, feeding calves with milk of tuberculous cows, killing the germs of tuberculosis in milk, [illegible] milk and cream, and dairy salt.

Farmers' reading courses, L. H. BAILEY (*U. S. Dept. Agr., Office of Experiment Stations Bul. 72, pp. 36*).—Farmers' reading courses in the United States have been largely organized and engineered by the agricultural colleges and experiment stations of the different States. Their object is to bring within the reach of farmers opportunity for securing systematic instruction under the direction of competent men on subjects affecting farm interests and farm life. The present bulletin treats of the historical development and present status of these courses in America. Outlines of the reading courses as conducted by agricultural colleges in Ontario, Pennsylvania, Michigan, New Hampshire, Connecticut, New York, West Virginia, and South Dakota are given with lists of the books used and mention made of ventures along the same lines in other States. In the appendix samples of lesson [illegible] and question papers issued in connection with the reading courses in some of the different States are given as are also samples of membership cards, application blanks for membership, etc. The different courses are commented upon and special features of the different systems pointed out and suggestions given regarding the conduct and management of farmers' reading courses.

Farmers' reading courses (*U. S. Dept. Agr., Farmers' Bul. 109, pp. 20*).—This is an abridgment of the above bulletin.

Books for farmers, stockmen, dairymen, and fruit growers, J. B. REYNOLDS (*Ontario Dept. Agr., pp. 8*).—Notes are given on the value and use of a farm library, and some 30 books on agricultural topics are recommended for this purpose and their contents summarized.

Agriculture and dairying in Scotland, J. C. HIGGINS (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 213–223*).

Rise and growth of agricultural education, J. D. WALTERS (*Industrialist, 26 ([illegible]), No. 24, pp. 327–334*).—The rise and development of agricultural colleges, experiment stations, and farmers' institutes in the United States are discussed.

Botanical institutions and the agricultural organization of Java and Ceylon, G. CLAUTRIAU (*L'Ing. Agr., 10 (1899), Nos. 4, pp. 301–328; 5, pp. 345–374*).

Report on crops, live stock, etc., in Manitoba (*Dept. Agr. and Immig. [Manitoba] Bul. 60, pp. 12*).—A brief summary of the yield of the various crops of the Province in 1899, data on dairy products and live stock, and the rainfall for each month from April to October.

Farm animals in Denmark, 1898 (*Ugeskr. Landm., 44 (1899), No. 35, p. 440*).—According to a recent bulletin of the Statistical Bureau the number of farm animals in Denmark, July 15, 1898, was as follows: Horses, 449,264; cattle, total, 1,743,440 (bulls and steers, 111,186; milch cows, 1,067,138; heifers and calves, 565,116); sheep, 1,074,413; goats, 31,803; swine, 1,178,514. Poultry: Chickens, 8,748,428; turkeys, [illegible]2; ducks, 803,217; geese, 210,907. Rabbits, 81,475; number of beehives, 118,178.—[illegible] WOLL.

American animals and animal productions in Great Britain, W. H. BRAY (*U. S. Dept. Agr., Bureau of Animal Industry Rpt. 1898, pp. 440–462*).—This includes data and discussion relative to the importation of cattle and horses into Great Britain, rules for the London provision trade, average weights of provision packages, prices of animal products in London, and an account of the cheese trade with the United Kingdom.

NOTES.

MISSOURI STATE FRUIT EXPERIMENT STATION.—This station was established by an act of the last State legislature, which appropriated $15,000 for the purpose for two years. A commission appointed by the governor to select a suitable site decided upon the town of Mountain Grove, which is practically in the center of the Ozark country. The town of Mountain Grove donated 198 acres of land for the use of the station. Active operations were not commenced until the beginning of the present year, so that the total appropriation of $15,000 is available for this year's work. J. T. Stinson, formerly horticulturist of the Arkansas Station, was elected director. Over 10 acres of land have been planted in fruits and berries the past spring. The contract has been let for the erection of the buildings, which will consist of an office and laboratory building, residences for the director and for the foreman, and a barn. The station is under the control of a board of trustees appointed by the governor. This board consists of J. C. Kerby, president, West Plains; M. T. Davis, treasurer, Aurora, and L. O. Hailey, secretary, Ava.

NEW MEXICO COLLEGE AND STATION.—John J. Vernon, formerly assistant horticulturist of the Iowa Station, has been appointed agriculturist and horticulturist in the college and station, and entered upon his duties May 1.

OHIO STATION.—The last general assembly enacted a law providing for the inspection of nurseries and orchards in the State for the San José scale, black knot, peach yellows, and other dangerous insect and contagious diseases of trees, shrubs, vines, etc., and the compulsory treatment of infected orchards, or their destruction when necessary. The station is charged with the enforcement of this law, and an appropriation of $15,000 was made for this purpose during the two years 1900 and 1901. Lowell Roudenbush has been appointed horticultural inspector and will have immediate supervision of the work. The following appropriations were made by the general assembly for the two years 1900 and 1901: Expenses of board of control, $1,200; bulletin illustration, $800; substations for field experiments, $4,200; special work in entomology, botany, chemistry, and horticulture, $7,500; investigation and prevention of tuberculosis and other diseases of cattle, $6,000; general repairs, labor, and supplies, $7,000; new construction, $4,850. Total, $31,550.

SOUTH CAROLINA COLLEGE AND STATION.—A. P. Anderson, who several years ago was botanist in the college and station, has been elected entomologist, and will enter upon his duties June 1. A. T. Smythe, of Charleston, has been added to the station committee.

TEXAS COLLEGE.—The summer school, which opens at the college June 18, will include among others courses in agriculture, horticulture, and manual training. The courses will continue for six weeks and are open to both sexes.

MISCELLANEOUS.—According to a recent number of Science, "An International Congress of Meteorology is to be held at Paris from September 10 to 16 of the present year. The president of the Commission d'Organisation of the congress is M. Mascart, director of the Central Meteorological Bureau of France. The secretary is M. Angot. Membership in the congress may be had on payment of 20 francs. The preliminary programme includes a long list of subjects in meteorology proper, as well as in oceanography and terrestrial magnetism and electricity."

A botanical garden and experiment station has been established at Coquilhatville, in the Congo Free State.

EXPERIMENT STATION RECORD.

VOL. XI. NO. 11.

Within the past few months the agricultural colleges and experiment stations of this country have lost by death two of their most able friends and supporters, who for many years had been actively associated with their work. Both were influential in securing the national legislation leading to the establishment of the experiment stations, and each served with distinction for a term as president of the Association of American Agricultural Colleges and Experiment Stations, in the proceedings of which they took an active part from the first.

James Henry Smart, who died February 21 at the age of 59 years, had been engaged in various lines of educational work for over forty years. He served successively as teacher in the public schools of New Hampshire, his native State, principal of a school at Toledo, Ohio, and superintendent of schools at Fort Wayne, Ind., occupying the latter position for a period of ten years. From 1874 to 1880 he was superintendent of public instruction in Indiana, during which time he revolutionized the school system of that State, and placed it in the front rank of American school systems. His association with agricultural education commenced with his election to the presidency of Purdue University in 1883, which he occupied with signal ability until his death.

Dr. Smart took a deep interest in the colleges of agriculture and mechanic arts and the agricultural experiment stations, and he thoroughly appreciated the value of these institutions in the educational system of the country and for the general uplifting and advancement of agriculture. He was one of the leading advisers in the framing of the Hatch Act, providing for the establishment of the stations, and he took an important part in securing the passage of the Morrill Act of 1890, increasing the support of the colleges.

At two different times Dr. Smart served as director of the Indiana Station, and at all times he evinced a deep interest in its work and in bringing the results of its teachings home to the farmer.

Although nearly blind for the last few years of his life, with the aid of an assistant he kept remarkably well informed of events in the educational world, and when his health permitted he continued his college work with indomitable courage and energy. To his tireless energy and wise judgment is largely due the development of a weak and struggling institution, with a small attendance, into one of the largest and most prosperous technical schools in the country, with greatly increased endowment, superior equipment, and an attendance of over 800 students from different parts of the United States.

George Espy Morrow, who died at Paxton, Ill., March 27, 1900, was one of the pioneers in work in agricultural education and research in this country. Practically his entire mature life was devoted to the advancement of agriculture. Early in his career he was engaged for some ten years in editorial work, being connected with a number of different agricultural papers during that time. In 1876 he accepted the position of professor of agriculture in the Iowa Agricultural College, but he occupied the chair only a few months before he was elected to a similar professorship in the Illinois Industrial University (now the University of Illinois). The latter position he occupied for nearly eighteen years. On the organization of the experiment station in 1888 he was made agriculturist and a member of its board of direction. He was president of this board of direction from 1892 to 1894, which placed him in charge of the executive work of the station.

In 1894 Professor Morrow assumed the presidency of the Oklahoma Agricultural College, and the following year he was also made director of the experiment station connected with the college. He served in this dual capacity until failing health compelled his retirement from active service in 1899. He then went to his farm at Paxton, Ill., where the remaining months of his life were spent.

Professor Morrow was a voluminous writer, especially on agricultural subjects, and through this medium and his farmers' institute work, to which he was peculiarly suited, he exerted a very marked influence for the improvement of methods of agriculture in Illinois. His presidential address before the Association of American Agricultural Colleges and Experiment Stations in 1894 was the beginning of a deeper interest in the method of teaching agriculture. He there urged the importance of so systematizing the subject as to reduce it to a better pedagogical form, and commended this work to the association as one of the most useful and far-reaching which it could take up. Since that time there has been some consideration of the subject at nearly every meeting, resulting finally in the appointment of a special committee, which has made several valuable reports.

Some of Professor Morrow's most effective work was done near the close of his career, in Oklahoma. The present prosperous condition of the agricultural college and experiment station of that Territory and the era of good feeling toward the institution are very largely attributable to his influence and labors. Not only did he materially strengthen the institution itself, but he stimulated an interest in higher education, a pride in the agricultural college, and a popular sentiment for its liberal support and freedom from political interference. He left behind him there an impression which will be felt for many a day.

RECENT WORK IN AGRICULTURAL SCIENCE.

CHEMISTRY.

Chemical methods for ascertaining the lime requirements of soils, H. J. WHEELER, B. L. HARTWELL, and C. L. SARGENT (*Jour. Amer. Chem. Soc., 22 (1900), No. 3, pp. 153–177*).—Various methods proposed for the determination of the acidity of soils are discussed, and tests of a number of them are reported.

The methods tested and the conclusions reached are as follows:

"(1) Moistening the soil with water, then bringing it in contact with blue litmus paper and noting with what rapidity and to what extent it reddens the paper as compared with some soil whose character is already well known. This method is highly effective in the hands of a close observer who has had much experience in testing soils of known character.

"(2) Treatment of the soil with water to which a little ammonium hydroxid (ammonia water) has been added and noting whether, after settling, the liquid has assumed a dark brown or black appearance. This test applies only where the acidity is due in a considerable measure to acid organic substances. It may not apply in all sections of the country, as shown by Snyder, in Minnesota, but it has thus far proved a very useful and reliable test with Rhode Island and certain other New England and New York soils containing considerable quantities of humus. Gravimetrically applied, this is the method of Müntz.

"(3) The method employed by Holleman for determining the lime requirement of stiff clay soils in Holland, based upon the amount of lime (calcium oxid) removable by extracting with carbonated water. This method has given little promise of usefulness in testing our upland acid soils.

"(4) The method of Tacke for determining the relative acidity of peat (moor) soils of North Germany based upon the amount of carbon dioxid which the acid ingredients of the soil can expel from calcium carbonate at ordinary temperatures in an atmosphere of hydrogen. This method has not seemed to be applicable to our acid upland soils.

"(5) The determination of the total humus by a modification of the Grandeau method, which consists in removing the lime and magnesia from their combinations with the humus by treatment with dilute hydrochloric acid, and then dissolving the humus in ammonium hydroxid (ammonia water) and estimating the amount dissolved. In our granitic soils containing considerable quantities of humus, this method gives results standing in somewhat definite relation to the lime requirements.

"(6) Determinations of the amount of lime (calcium oxid) which can be dissolved by weak hydrochloric acid by digestion at a high temperature for several hours (official method of the Association of Official Agricultural Chemists). This method furnishes no reliable basis for arriving at the lime requirement of our acid upland soils.

"(7) Method by titration, based upon measuring the number of milligrams of nitrogen combined as ammonium salts and held by the soil when it is treated in a given way and for a given time with a very dilute solution of ammonium hydroxid.

"The results by this method agree more closely with the crop tests than by any other method tried, though it is closely approximated to, by the gravimetric determination of the humus dissolved from the soil by extraction with ammonium hydroxid without the previous removal of the lime and magnesia.

"(8) Method based upon the comparison of the color of the extract made from soils by treating directly with ammonia water, with the color of such an extract prepared from a like quantity of soil of known character. It seems probable that where the acidity is due largely to acid organic substances this method may give fairly good results The rapidity with which tests may be made by it is an important practical point in its favor as compared with the method as proposed by Müntz.

"(9) Method based upon the amount of carbon dioxid expelled by a given amount of soil from calcium carbonate when the two are heated together at the boiling point in the presence of water. This method gives promise of much value if the period of heating is made uniform and very brief, and if the carbon dioxid liberated is easily and accurately determined."

Phosphates and the humic acid method, W. HOFFMEISTER, (*Landw. Vers. Stat., 52 (1899), No. 5-6, pp. 329-345*).—The author reports studies with various slags, which indicate that his humic acid method (E. S. R., 10, p. 818) furnishes a reliable means of determining the relative value of different phosphates. In this method phosphoric acid goes into solution in combination with alkalis, while the lime separates out largely in the form of carbonates or humates. This reaction occurs most readily in those phosphates in which the lime is most easily thrown out of combination, namely, in superphosphates and Thomas slag. A considerable amount of silicic acid always passes into solution with the phosphoric acid, and it appears that the solubility of the latter increases with that of the former, so that more phosphoric acid is dissolved when fresh sand (which contains some soluble silica) is used in carrying out the method. The author believes that the soluble silicic acid of the soil is an important factor in determining the availability of phosphates applied as fertilizers, and suggests that the supply of soluble silica may become periodically exhausted. Several soils were examined by the method with results which indicated that in connection with pot experiments with fertilizers it will prove useful for determining the availability of the fertilizing constituents of the soil.

More specific directions than were contained in the previous article regarding the treatment of the humic acid extract are given as follows: The extract is made up to 2.5 liters. Two liters of the solution, corresponding to 4 gm. of Thomas slag, is filtered, evaporated to dryness, taken up in water, and again evaporated in order to drive off any ammonium carbonate that may be present. The residue is dissolved in hydrochloric acid, the solution evaporated to dryness, dilute hydrochloric acid added, and the solution filtered. An aliquot part of this solution is boiled with nitric acid and the phosphoric acid precipitated by the usual method.

Analysis of portion of ash of excrements insoluble in hydrochloric acid, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 86, 87*).—**That portion of the ash of feces from steers fed timothy hay which was insol-**

able in hot hydrochloric acid was found to have the following percentage composition: Silica 89.52, ferric oxid 1.92, manganic oxid 0.15, alumina oxid 0.01, calcium oxid 2.65, magnesium oxid 0.08, potassium oxid 4.73, and sodium oxid 1.34.

"The question is whether this matter insoluble in strong hydrochloric acid, is formed in the animal body or in the plant or, perhaps, in the process of incineration. It is presumed, of course, that no insoluble mineral matter can enter the plant as such through the roots."

The loss of nitrogen in the drying of urine, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 95-100*).—In connection with digestion experiments with steers, a number of experiments were made to determine the cause of the observed loss of nitrogen in drying urine. The nitrogen in the urine was determined in several different ways. Tests were also made to learn whether an aqueous solution of urea with and without sodium phosphate lost weight when absorbed in sand and dried. The results of the tests, however, were not regular, and definite conclusions were not drawn.

"The decomposition of urea seems to occur more readily in a dilute solution than when concentrated, and more is decomposed in the presence of sodium phosphate than in aqueous solution. The mucous and coloring matters in urine are, however, also instrumental by their own alteration to act upon the urea present so that the writer is unable to suggest any method of drying urine which would yield, without loss of nitrogen, the whole of the solids of a certain volume.

"This, of course, must be taken into account when making calorimetric determinations with the dried materials."

The loss of nitrogen in the drying of feces, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 87-95*).—A number of experiments were made to determine the character and amount of loss of nitrogen of the feces of steers fed timothy hay. When the feces were sterilized in closed bottles and kept some time, there was no loss of nitrogen. Samples were dried in air at 70° C., and afterwards in an oil bath or oven at 101° C.; in an oven at 101°, and over sulphuric acid. Samples of fresh feces were treated with water and distilled. A number of determinations were made of the nitrogen in the fresh material and in samples completely dried in the usual laboratory methods. The results of the test follow:

"The excrements of cattle on being voided have an alkaline reaction, owing to the presence therein of ammonia; they likewise contain skatol and sudol. This causes loss in nitrogen by drying, whether done by heat or water absorbing substances, which seems proportional to the intensity of heat, the length of time and the completeness of the drying.

Under the conditions prevailing in our digestion experiments, where drying was effected at a temperature not exceeding 70° C., and the dried material retained from 8 to 7 per cent of moisture, the loss in nitrogen calculated for water-free excrements amounted on an average to 0.08 per cent. It is possible by proper management to effectively sterilize and preserve fresh excrements so that no nitrogen is lost and, perhaps also, the water contents are not altered."

Proximate composition and calculated thermal value of feeds and feces, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 102–105*).—The author compares the determined heat of combustion of a number of feeding stuffs and of the feces of 3 steers with similar values calculated on the basis of the thermal value of the proximate constituents of the materials. The calculated heat of combustion of feces was from 6.82 to 8.42 per cent lower than the value as determined. The calculated heat of combustion of the feeding stuff was 3.49 per cent lower. The results are discussed at some length.

"The four proximate principles, commonly determined in a so-called feed-stuff analysis, each consist of groups of bodies which, while having something in common, yet differ from one another in composition, digestibility, and properties in general. I hold this to be true even in the case of crude fiber, where, perhaps, a reasonable doubt might be entertained of its composite character."

The determination of fiber in feeding stuffs, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 105–111*).—A comparison of the official method with Müller's bromin and ammonia method, using excelsior, cornstalks, and corn leaves. The constituents of the crude cellulose obtained from the 3 materials with the 2 methods are described and the amounts estimated. The constituents other than fiber were also determined, and the results are summarized as follows, the crude fiber being determined in Nos. 1, 3, and 5 by the official method and in Nos. 2, 4, and 6 by the bromin and ammonia method:

Analysis of excelsior, cornstalks, and corn leaves.

	Excelsior.		Cornstalks.		Corn leaves.	
	1.	2	3.	4.	5.	6.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
Ether extract	1.08	0.98	1.79	1.80	1.87	1.70
Alcohol extract	3.71	3.75	27.45	27.17	16.91	16.88
Crude ash	.84	.84	3.72	3.71	10.36	10.37
Protein	1.26	1.26	8.53	8.50	14.90	14.93
Fiber	46.73	46.26	29.52	29.34	23.94	23.21
"Vasculose"	16.11	(16.11)	.69	(.69)	.38	(.38)
"Pectose"	(17 60)	17.60	(11.36)	11.36	(15.75)	15.75
Carbohydrates	12.67	13.20	16.94	17.43	15.89	16.78
	100.00	100.00	100.00	100.00	100.00	100.00

The effect of heating the samples under pressure in a Papin digester for from 1 to 6 hours was tried, and the resulting fiber was examined. The conclusion was reached that "the digester method is evidently not adapted to increase our knowledge of the fibers in feeding stuffs."

Lactic acid determination by means of alcohol, G. WALCK (*Pharm. Ztg., 44 (1899), pp. 906, 907; abs. in Chem. Centbl., 1900, I, No. 4, p. 267*).—Soxhlet has shown that previous to the beginning of lactic acid production in fresh milk a certain time intervenes in which the lactic acid germs increase without any increase in the acidity of the milk. This period, which depends upon the temperature and the condition of the milk, Soxhlet has called the incubation period, and he holds that milk should not be used beyond this period.

To determine the exact degree of acidity milk is titrated, using phenolphthalein as indicator, but in some north German creameries this is determined approximately by the behavior of the milk on the addition of 68 per cent alcohol. The author studied the relation between degree of acidity and the curdling with alcohol, and found that the amount of 68 per cent alcohol required to curdle milk diminished as the degree of acidity increased. Milk which did not curdle when mixed with an equal volume of alcohol was found to have a small degree of acidity, did not curdle by cooking, required at most 2 cc. of decinormal alkali to neutralize 10 cc. of milk, and was suitable for children. Milk which under similar conditions gives flocculent curdling is said to be past the incubation period and no longer suitable for children. Milk which curdles on the addition of a small amount of alcohol is sour, will curdle when cooked, and is unfit for consumption.

This simple method the author believes to be useful for the rapid and simple determination of the approximate acidity of market milk.

Proceedings of the sixteenth annual convention of the Association of Official Agricultural Chemists, held at San Francisco, Cal., July 5, 6, and 7, 1899 (*U. S. Dept. Agr., Division of Chemistry Bul. 57, pp. 130*).—This is a detailed account edited by the secretary of the association, H. W. Wiley. For a summary of the proceedings see E. S. R., 11, p. 204.

Bibliography for the use of the Swiss Government analytical laboratories and similar institutions (*Litteratur-Verzeichniss fur die Schweizerischen kantonalen Laboratorien und ahnliche Untersuchungsanstalten. Basel: Wakernagel; rev. in Ztschr. Untersuch. Nahr. u. Genussmtl., 3 (1900), No. 4, p. 299*).—This compilation was made for the Society of Swiss Analytical Chemists at their yearly meeting in Lugano in 1899.

Investigations on caramel bodies, F. STOLLE (*Ztschr. Ver. Deut. Zuckerind., 1899, Nos 524, II, pp 800–807; 525, II, pp. 839–842*).

The determination of phosphorus in organic compounds, C. MARIE (*Bul. Soc. Chim. Paris, 3. ser., 23 (1900), No. 1, pp. 44, 45*).

On the volumetric determination of boric acid, A. STOCK (*Compt. Rend. Acad. Sci. Paris, 130 (1900), No. 8, pp. 516, 517*)

Tests for cotton-seed oil and sesame oil in fats, J. LYNE (*Ind. Lait., 25 (1900), No. 15, pp. 114, 115*).—Methods of detecting these oils in butter, including the reactions of Becchi, Baudouin, and Halphen, are briefly discussed.

Volumetric determination of the dirt in milk, A. SCHLICHT (*Ber. Chem. Hyg. Untersuchungsamtes. Stadt Stralsund, 1894–1899, p. 21, fig. 1; abs. in Ztschr. Untersuch. Nahr u. Genussmtl., 3 (1900), No. 5, p. 343*).—The milk is whirled in a centrifuge in a tube drawn out at the bottom into a narrow graduated neck.

Handbook of practical hygiene, D. H. BERGEY (*Easton, Penn.: Chemical Pub. Co., pp. 164*).—"A short and concise laboratory guide for the sanitary analysis of air, water, soil, and the principal food materials; also a chapter on the ventilation of buildings."

Estimation of the acidity of milk by means of alcohol, G. WALCK (*Pharm. Ztg., 44 (1899), pp. 906, 907; abs. in Ztschr. Untersuch. Nahr. u. Genussmtl., 3 (1900), No. 5, p. 343*).

Human milk, I. CALLARI (*Gaz. Osp. e Clin., 21 (1900), No. 24, pp. 248–250*).—Analyses are reported.

Detection of artificial organic coloring matters by means of spectral analysis, J. FORMÁNEK (*Spektralanalytischer Nachweis kunstlicher organischer Farbstoffe. Berlin: J. Springer, 1900, pp 10+196, ill.; rev. in Ztschr. Untersuch. Nahr. u. Genussmtl., 3 (1900), No. 5, pp. 375, 376*).

Analyses of resins, balsams, and gums; their chemistry and pharmacology, K. DIETERICH (*Analyse der Hartze, Balsame und Gummiharze nebst ihrer Chemie und Pharmakognosie. Berlin: J. Springer, 1900, pp. XVI+286*).—A text-book designed for use in scientific and technical laboratories.

Ash analyses of some common plants, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, p. 83*).—Tabulated analyses are given of purslane (*Portulaca oleracea*), plantain (*Plantago major*), Kentucky coffee beans, and thorns of honey locust.

BOTANY.

The physiological rôle of mineral nutrients, O. LOEW (*U. S. Dept. Agr., Division of Vegetable Physiology and Pathology Bul. 18, pp. 60*).—In this bulletin is presented what has been accomplished by the author and others in determining the physiological rôle of mineral nutrients in the plant and animal body. After a historical statement of the subject, general remarks on the mineral constituents found in organisms, and the general value of mineral salts considered from an ecological standpoint, the author takes up their physiological rôle. As physiological elements, he considers potassium, sodium, calcium, magnesium, iron, phosphorus, chlorin, iodin, carbon, hydrogen, nitrogen, oxygen, and sulphur. Of these, magnesium and potassium salts and phosphoric acid are held to be essential to every living cell. Sodium salts are not essential for the physiological uses of plants, but are for those of animals. Calcium salts are necessary to all higher plants and animals.

In the present bulletin the author considers the physiological rôle of phosphoric acid, iron compounds, halogen compounds, alkali salts, and calcium and magnesium salts. Phosphoric acid is said to be essential to the production of lecithin and chromatin and plastin, the most essential constituents of the nucleus and plastids. Cell division can only take place in the presence of an abundant supply of phosphoric acid. The chief function of lecithin is said to be in respiration, the fat being presented to the protoplasm in the form of lecithin. Phosphoric acid is also necessary for chlorophyll production, and potassium phosphate is an important cell constituent.

The relation between chlorophyll and hæmoglobin in the blood is pointed out, and the necessity of iron to both is shown. Among the fungi, iron is not essential, and although manganese is often present in the ash of some of the higher plants to a greater extent than iron, it can not replace it in its physiological action.

The action of the chlorids of potassium and soda is stated, the other compounds with chlorin being considered injurious. While beneficial to some plants in certain stages of growth, an excess of the limited amounts of the potassium and sodium chlorids required proved highly injurious.

Among the alkali salts, potassium is shown to be important for the formation of starch and protein. Sodium salts can be disposed of by many plants, and it is thought that compounds of soda exert a favorable action in the ripening process of cereals. Sodium, it is claimed, can not replace potassium in the preparation of organic substances in plants.

The physiological rôle of calcium and magnesium salts is discussed at considerable length. Among other things, the author states that "magnesium salts are poisonous in the absence of calcium salts, while the absence of magnesium salts in an otherwise complete culture solution will lead to a gradual stoppage of development. The formation of the nuclei and plastids requires calcium as well as magnesium salts, the former for the production of calcium nucleo-proteids and the latter for making possible the assimilation of phosphoric acid."

On the absorption of soluble salts by plants, E. DEMOUSSY (*Ann. Agron., 25 (1899), Nos. 11, pp. 497–548; 12, pp. 561–607, dgms. 4*).—The author conducted a series of experiments with peas, maize, colza, buckwheat, crimson clover, rye grass, wheat, and rye, to test their capacity to absorb through their roots the nitrates of potassium, calcium, sodium, magnesium, strontium, and barium, chlorids of potassium and sodium, and the bromids and iodids of potassium; also to ascertain the selective capacity of plants in separating a given substance from a mixed solution.

Seeds were germinated in distilled water and the plantlets transferred to vessels containing known quantities of the salt under investigation. It was found that the abundance of nitrates in a plant depends upon the readiness with which they are separated from dilute solutions. Once within the plant, they are protected from the solvent action of the medium as long as the plant is alive, but are quickly diffused after the death of the plant.

Provided the base with which the nitric acid is in combination is not poisonous, there is no difference in the absorption of the different salts. When presented alone, sodium nitrate is taken up as readily as potassium nitrate, and the nitrates of calcium and magnesium as well as those of sodium and potassium. The nitrates of lithium, strontium, and barium are absorbed very slowly and their noxious effect is soon shown. The chlorids act in a similar manner to nitrates. Their rôle in the plant's economy is thought to be greatly inferior to that of the nitrates.

Investigations on the selective power of plants show that when the cultures contain nitrates and chlorids of the same base, more of the nitrate is taken up by the plant. More potassium is taken than sodium and in the presence of potassium sodium is not absorbed. Calcium is not able to prevent the absorption of sodium.

Some physiological effects of hydrocyanic-acid gas upon plants, W. G. JOHNSON (*Sci. Amer. Sup., 48 (1899), No. 1249, pp. 20026, 20027, figs. 6*).—This is a revision of a paper read by the author before the American Association for the Advancement of Science, August, 1899.

The history of the use of hydrocyanic-acid gas as an insecticide is briefly reviewed and a number of experiments outlined, in which the effect of the gas on the foliage and vitality of a number of varieties of trees are reported. A number of thoroughly dormant trees were subjected for 30 minutes to gas generated by different amounts of potassium cyanid. No injury was noted on any of the trees.

In 1897 another series of experiments was conducted, in which trees in full foliage were fumigated at all hours of the day and in all conditions of weather. Within 5 minutes after the tents were removed, the petioles of the leaves were black to the base and the leaves fell a few days later. The following spring the leaves came out as normally and there was about one-fourth as much fruit upon the trees as on those which had been fumigated with a normal strength of the cyanid. Trees fumigated at night with double the quantity were comparatively little injured. The fruit buds, however, were destroyed to some extent.

These experiments seem to indicate that the gas was most injurious to foliage during sunshiny days, late in the fall, between 9 a. m. and 4 p. m.; that dormant leaves in fruit trees treated with 0.2 gm. per cubic foot were uninjured; that burned leaves fall readily, and that treatment in the morning before 9 o'clock and in the afternoon after 4 o'clock, even in sunshine, affected the leaves but little, while trees treated at night with normal doses are not injured at all.

Other experiments are outlined, and in conclusion the author states that "we can say that the danger point where well-matured nursery stock is injured by hydrocyanic-acid gas is so far above the standard used that practically no damage can result from an overdose. With apple and pear there is practically no injury even with the strongest applications. Plum is slightly more susceptible, being injured at 0.65 gm. per cubic foot. In the peach the injury began at 0.5 gm. in well-matured trees, but it is fatal in low-grade trees at above 0.18 gm."

Photosynthesis by light which has passed through leaves, E. GRIFFON (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 26, pp. 1276-1278*).—The results of a number of experiments in which light made to pass through leaves exerted upon the photosynthesis of other leaves are reported. In the case of sycamore, maple, chestnut, beech, and mulberry, the leaves having approximately the same thickness, there was considerable carbon assimilation when one leaf was superimposed upon another, and the same was true, but to a less extent, when large thick leaves, such as barberry, *Prunus cerasus*, etc., were used. However, when two or more leaves were superimposed under the same condition, there was generally a slight liberation of carbon dioxid. The passage of the light through a single leaf still contained sufficient force to serve for the photosynthesis of the leaves which were shaded. The light traversing the leaves has its photosynthetic power reduced not only on account of the absorption of the chlorophyll through which it passes, but also by absorption through any uncolored portions of the leaves, the tissue of the leaf, and the protoplasm.

If a leaf blanched with alcohol be placed over another, the energy of assimilation is reduced from 2 to 2½ times, and a natural albinal leaf reduces it two or more times. A green tobacco leaf placed over another reduces the photosynthesis of the under leaf 5 times as much as an albinal leaf of the same plant.

From these investigations it is apparent that the principal cause of the reduction of assimilative power of leaves shaded by other leaves is due to the absorption by the chlorophyll.

Photosynthesis and the coloration of plants, E. Griffon (*Ann. Sci. Nat. Bot., 8. ser., 10 (1899), No. 1-2, pp. 1-123, pls. 4*).—In an extended series of observations the author has sought to ascertain the relation between the assimilative energy of plants and their color. The experiments are grouped into classes as follows: Phanerogams with dark green foliage and those having other colored leaves than green, parasites and saprophytes; and the action of color in connection with light, heat, and various salts. The specimens under examination were placed in a form of apparatus containing air of known composition, and after the usual exposure analysis showed what change had taken place. In this way a proportion was established between the different plants under the varying conditions.

The coloration of the leaves of phanerogams was found to vary widely. The intensity of the green of the chlorophyll is said to depend upon the thickness and differentiation of the mesophyll and upon the number, size, color, and distribution of the chromoleucites. All these factors have an important bearing upon photosynthesis. In some plants the green may be masked by anthocyan and erythrophyll, or the chlorophyll may be wholly wanting as in variegation. It was found that in nearly related species and varieties of plants differences in the intensity of coloration were apparent. In the case of cereals, lettuce, begonias, and fuchsias, those having deep green leaves possessed a greater assimilative energy than the light green ones. In the case of peaches, plums, cannas, and chrysanthemums the pale green leaves assimilated most actively. Among the plants having various colored foliage it was found that red beets, purple filberts, *Prunus pissardi*, purple sycamore, cannas, arums, and pelargoniums assimilated less than varieties of the same plants having dark green leaves. In the case of red atriplex and beech, which have the coloring matter in their epidermis, and the purple barberry, whose coloring matter is in the palisade, their assimilative energy equaled that of species of the same plants which were rich in chlorophyll. In leaves which redden and fall in the autumn the liberation of carbon dioxid is said to take place for some time after the appearance of the red coloration. There is some little assimilation, but it is masked by the respiration. The chloroleucites after awhile are completely disorganized. The anthocyan appears in all the cells and the leaves take on the red coloration. They continue to respire for a time, but soon perish. Grape leaves which do not normally take on a red coloration sometimes behave during August and September in a manner analogous to that just described. This affection, which is known as "rougeot," is in reality an autumnal reddening brought about accidentally and prematurely by unusual meteorological conditions.

The investigations of the parasites and saprophytes showed that the terrestrial orchids occupy an intermediate position, so far as photosynthesis is concerned, between the green leaved plants and those which live wholly as saprophytes. *Limodorum abortivum*, a plant which possesses highly colored foliage, although containing a considerable quantity of chlorophyll, seems to be without the ability to utilize the carbon dioxid of the air.

Among those plants which are able to form chlorophyll in darkness, the piñon pine decomposes carbon dioxid when brought into the light. Whether the chlorophyll in this case differs from that produced in the light is not determined. Intensity of green coloration and structure were found to vary with the refrangibility of the rays to a considerable extent. Heat, within certain limits, increases the thickness and differentiation of the mesophyll of leaves and the dimension and color of the chloroleucites, and as a result increases the photosynthetic ability of the plant.

The author states that it has long been known that nitrates and the salts of iron favor the production of chlorophyll and as a result increase the assimilative energy of the plants. Copper salts when added to nutrient solutions in very small quantity, as 1 to 10,000 or 1 to 20,000, while attacking the roots and retarding growth, increase the color of the chloroleucites and also the intensity of the color of the plant, assisting materially in the assimilative energy. Sodium chlorid is unfavorable to the formation of chlorophyll, and gives to plants a greenish yellow or pale green color, which is quite characteristic. At the same time the mesophyll of the leaf is thickened, but the structure is not favorable to an increased utilization of carbon dioxid. An excess of lime, among other causes, results in chlorosis of a number of plants. These plants take on a yellowish color and the photosynthesis is reduced to one fifth or one-sixth that of normal leaves in case of the pear and grape.

The presence of copper in plants and the quantity they may contain, E. HECKEL (*Bul. Soc. Bot. France, 46 (1899), No. 1–2, pp. 42, 43*).—It is stated that *Polycarpœa spirostylis* so frequently contains copper that in Australia its growth is considered an indication of the presence of copper. Analyses of the above plant are quoted where 30 mg. of copper per kilogram of dry weight were found, and a second content of 560 mg. per kilogram dry weight where plants grew in soil very rich in copper.

The author states that the seeds of *Quassia gabonensis* were observed to contain considerable quantities of copper, and upon analysis 100 gm.

of the ash of the entire seed gave 0.698 gm. of copper, and the ash without the seed coat gave 0.254 gm., showing that the greater portion was in the seed coat.

In a similar way *Viola calaminaria* is said to contain considerable quantities of zinc, and the presence of the plant usually indicates zinc in the soil.

The root tubercles of plants, L. HILTNER (*Selsk. Khoz. i Lyesov., 192 (1899), Feb., pp. 425–462*).—After summarizing the previous investigations relative to the assimilation of free atmospheric nitrogen by the organisms in the root tubercles of leguminous and other plants, the author states his views as to the processes which take place within the tubercle. It is claimed that assimilation of nitrogen can take place only after the development of the organism and establishment of reciprocal relations between it and the host plant. The ability to transform free nitrogen into a form assimilable by the plant is not confined to a single genus of bacteria or fungi. In the tubercles of legumes are found true bacteria, in eleagnus are organisms intermediate between bacteria and fungi. in the Cyperaceæ are found entorrhiza, and endotropic mycorrhiza in the tubercles of Podocarpus, and, according to some investigators, physiologically similar organisms are found in sago.

The author concludes that all the organisms in question appear as true parasites and are to a greater or lesser degree injurious to the host plants. The parasitic action of the tubercle organisms is shown by the secretion of certain peculiar substances. If a tubercle from an alder tree be triturated in sterilized water and filtered through a Chamberland filter and young alder plants inoculated with the filtrate, the root hairs of the alder begin to shrivel and deformities similar to those which take place on infection with the bacteria are produced, although no tubercles are found. It is as yet unknown whether these secretions aid in inducing the assimilation of free nitrogen.

The injurious influence of the secretory products disappears when the tubercles attain their final development, but since these products continue to form inside the mature tubercle the supposition is that they are immediately converted into substances harmless to the plant. Such a conversion takes place with the cooperation of the host plant by supplying the organism with a part of the nutritive substances produced by the plant. This is further corroborated by the fact that from legumes and alders bacteria can be grown only in nutrient media containing extracts from the roots of leguminous or alder plants. The exclusive preference which is shown by *Bacillus radicicola* to leguminous plants tends to prove that Leguminoseæ alone are capable of producing the substances necessary for bacteria, the nature of which is being investigated. Starch apparently serves only in part as a nutrient material for tubercle organisms, as is seen in the active tubercle containing more starch than can be immediately consumed.

The host plant not only tends to render harmless the metabolic processes of the parasite, but it offers direct resistance to the parasite. In leguminous plants, as well as in the alders, mucous threads are found soon after the infection inside many roots of the hairs. However, tubercles are not always found where mucous threads have appeared. The number of tubercles is comparatively small. In the case at least of the alder the tubercles are formed only when the mucous threads penetrate the root cells and reach the nuclei. Having attained this, they are no longer liable to absorption by the host plant. In tubercles in the process of formation the bacteria endeavor to protect themselves against the host plant by forming bacteroids and sporangia which present an increased surface for the absorption of gases. Owing to such an adaptation, they are enabled to construct from the atmospheric nitrogen albuminous compounds which are gradually taken up by the plant. By microchemical tests substances resembling albumin can be observed both inside and around the bacteroids in tubercles of legumes, alders, and eleagnus. These substances, which are of a faint green color, are soluble in water in the case of the legumes, but insoluble in case of the others, and are transported through the usual channels to the aerial portions of the plant.

Legumes and alders with active tubercles are resistant to a second infection by tubercle organisms, but they are not immune when the tubercles are inactive.

Toward the fall of the year, when the supply of carbohydrates on the part of the plant ceases, the process of assimilation of atmospheric nitrogen stops. The tubercle organisms are not all absorbed by the plant owing to its weakness at that time. In the remaining tubercles the nitrogen content falls to a minimum.

In conclusion the author claims that the relation between the tubercle organisms and their host plants is that of two contending parties. The bacteria draw on the nitrogen of the air in their endeavor to make up the deficiency of nitrogenous substances which are taken from them by the plant.—P. FIREMAN.

Lessons in botany, G. F. ATKINSON (*New York: Henry Holt & Co., 1900, pp. XV+365*).—This book is an abbreviated and simplified edition of a previous work by the author (E. S. R., 10, p. 611), and is designed for the use of pupils in secondary schools where short or half-year courses in botany are given.

The first chapter is devoted to a study of seedlings, and this is followed by chapters on shoots, buds, and protoplasm, after which the same order as that observed in the larger book is followed, the technical matter being to a great degree simplified.

Minnesota plant life, C. MACMILLAN (*Minnesota Bot. Studies, 3. ser., 1899, pp. 568, pls. 4, figs. 240*).—In this work the author seeks to give the reader in popular though exact language an idea of the diversified plant life of the State. The different groups of plants are reviewed in their natural order, some of the plant structures and behaviors described, and some ecological problems explained, the hope on the part of the author being to inspire a desire for a broader knowledge, a deeper interest, and a truer appreciation of plant life.

New or little known Mexican grasses, F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Cir. 19, pp. 4, fig. 1*).—The author describes a number of species of grasses which are new to science and gives notes on a number of others, all of which were collected by C. G. Pringle during the season of 1899. The new species and varieties described are: *Panicum pilosum macranthum*, *P viscidellum*, *P. multirameum*, *P. albomaculatum*, *Avena micrantha*, and *A. stipoides*.

Native and introduced grasses found at Stillwater., Okla., J. H. BONE (*Oklahoma Sta. Rpt. 1899, p. 87*).—A list of some 45 species of grasses is given, together with the common and scientific names, period of growth, and date of blooming.

Native food plants, J. H. MAIDEN (*Dept. Agr. New South Wales, Misc. Pub. 282, pp 65*).—A botanical description is given of a large number of Australian native food plants.

Inventory of foreign seeds and plants, O. F. COOK (*U. S. Dept. Agr., Division of Botany, Inventory 5, pp. 62*).—A list of species and varieties of plants recently introduced through the Section of Seed and Plant Introduction of this Department. Most of this material was collected in France, Italy, and Algeria by W. T. Swingle. In addition to this list, miscellaneous collections from a number of sources are mentioned.

Inventory of foreign seeds and plants, O. F. COOK (*U. S. Dept. Agr., Division of Botany, Inventory 6, pp. 15*).—This circular contains an inventory of foreign seeds and plants collected by B. Lathrop and D. G. Fairchild in Austria, Italy, and Egypt.

A revision of the western North American phloxes, E. NELSON (*Wyoming Sta. Rpt. 1899, pp. 1-36*).—This revision contains a summary of our knowledge of western species of phlox, together with descriptions of a number of new species and varieties. It was presented by the author as a thesis for a degree in the University of Wyoming.

A preliminary ecological study of the native and introduced plants of the vicinity of Columbia, Mo., F. P. DANIELS (*Missouri Sta. Rpt 1898, pp. 124-156*).—A study was made of plants in their native localities with special reference to their culture, conditions of soil, and climate and other environmental conditions A list of the flora of the regions is given, arranged according to the ecological distribution of the plants.

Culture experiments on the adaptation of plants to climate, G. BONNIER (*Compt. Rend. Acad. Sci. Paris, 129 (1889), No. 26, pp. 1207-1213*).—Notes are given on a number of investigations made under the author's direction, in which the effect of Mediterranean climate on a large number of plants is shown. The differences between the cultivated plants and those in the original conditions are pointed out. The author thinks that it is possible that a great number of plants may be able to change their form in order to adapt themselves to Mediterranean conditions.

Plasmolytic studies on the growth of cell membranes, O. REINHARDT (*Festschr. Schwendener, Berlin, 1899, pp. 41*).

On the cytological phenomena preceding and accompanying the formation of the teleutospores of Puccinia liliacearum, R. MAIRE (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 21, pp. 839-841*).—Notes are given on the various cytological changes which are observed in this fungus which is parasitic on the leaves of *Ornithogalum pyrenaicum*.

The fixation of carbon by leaves, H. T. BROWN (*Nature, 60 (1899), No. 1559, pp. 474-483, dgms. 3*).—Presidential address before Section C of the British Association for the Advancement of Science. Photosynthesis is described and some experiments on the rate of carbon dioxid assimilation are briefly outlined. A brief review of this address is given in *Jour. Hort., 51 (1899), No. 2661, p. 271.*

Protein synthesis in phanerogams, B. HAUSTEEN (*Jahrb. Wiss. Bot., 33 (1899), No. 3, pp. 417-486, figs. 2*).

The physiological significance of alcohol in the vegetable kingdom, P. MAZÉ (*Compt. Rend. Acad. Sci. Paris, 128 (1899), No. 26, pp. 1608-1610*).

On the presence of formaldehyde in plants, G. POLLACCI (*Bol. Chim. Farm., 38 (1899), p. 601; abs. in Chem. Ztg., 23 (1899), No. 36, Repert., p. 352*).—A number of experiments are briefly outlined from which the author concludes that formaldehyde is formed in green leaves in the sunlight.

Effect of arsenic on plants, R. Bouilhac (*Bul. Soc. Bot. France, 46 (1899), p. 64*).—A number of fresh water algæ are said to absorb arsenic acid from arsenates without apparent injury, while the growth of one (*Schizothrix lardacea*) appears more favorably influenced by arsenic acid than by phosphoric acid.

Influence of electricity on plants, H. Euler (*Ofver. K. Svensk. Vetensk. Akad. Förhandl., 1899, No. 56, pp. 609–629*).

The effects of the fog at Chiswick (*Gard. Chron., 3. ser., 26 (1899), No. 672, p. 356*).—Notes are given of the effect of prolonged fog on plants. The leaves became very tender and later appeared as though badly scorched. The worst injury appears to have been done to plants grown under glass.

The assimilation of atmospheric nitrogen by the mycelium of aerial parts of plants, L. Hiltner (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 24, pp. 831–837*).—On account of the reputed symbiotism between darnel and the fungus infesting it, cultures were made of the plant, comparisons being made with *Lolium italicum*, which is supposedly free from the fungus. There was apparently some gain of nitrogen in the darnel, but the author does not feel warranted in drawing conclusions from the experiment. The investigation is to be continued, when it is hoped to obtain well-developed seed, the fungus mycelium being much more abundantly developed in the seed than elsewhere.

Alinit: A bacteria of the soil (*Florists' Exchange, 11 (1899), No. 44, p. 1104*).

Is the Alinit bacterium a single species? R. Hartleb (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 21, pp. 706–712*).—Studies were made of *Bacillus ellenbachensis*, *B. megatherium*, and *B. subtilis*, and the author claims they are specifically distinct.

The assimilation of atmospheric nitrogen by Alinit bacteria, J. Stoklasa (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 10, pp. 350–354; 6 (1900), No. 1, pp. 22–24*).—The author reviews a number of experiments with wheat, in which it is claimed there was a marked gain due to Alinit inoculation.

Results of experiments with Alinit, O. Lehmann (*Deut. Landw. Presse, 26 (1899), No. 82, p. 938*).

Investigations of Alinit, W. Krüger and W. Schneidewind (*Landw. Jahrb., 28 (1899), No. 3–4, pp. 579–591*).—A report is given of experiments in the laboratory and pots with Alinit to determine its ability as an assimilator of atmospheric nitrogen. In the culture experiments beets, potatoes, oats, mustard, and rye were grown and comparisons made with and without Alinit and applications of nitrate of soda. In every case the application of the Chile saltpeter gave the greatest yields, and only with beets did the Alinit give any increase over the noninoculated lots. The conclusion of the authors is that in practice Alinit is without value.

On the hybrid fecundation of albumin, H. Devries (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 23, pp. 793–795*).—Notes are given by the author on a number of investigations on the immediate effect of cross fertilization on the development of endosperm of seeds. The examples cited are mostly from experiments conducted with sweet and starchy varieties of maize. Numerous cross-fertilization experiments were made with the result as shown by the seed that immediate effect of the pollen was very marked.

Investigations on Xenia of maize, C. Correns (*Ber. Deut. Bot. Gesell., 17 (1899), No. 10, pp. 410–417*).—A preliminary note is given of the author's investigations on the influence of pollen upon the endosperm as shown in the crossing of races and varieties of maize. A number of fundamental principles are laid down as to the prepotency of one or the other parents.

Some thoughts on hybridizing, W. A. Christy (*Amer. Florist, 15 (1900), No. 617, pp. 1044–1046*).—Popular suggestive notes on this subject.

Concerning the use of some well-known coloring reagents in microscopic investigations, M. Claudius (*Centbl. Bakt. u. Par., 2. Abt., 5 (1899), No. 16–17, pp. 579–581*).

METEOROLOGY.

Meteorological report, C. B. RIDGAWAY (*Wyoming Sta. Rpt. 1899, Met. Rpt. 1898, p. 24*).—A brief statement of the equipment of the station for meteorological observations, with tables giving daily observations on temperature, terrestrial radiation, relative humidity and dewpoint, atmospheric pressure, and wind movement at Laramie, Wyo., for each month of 1898, as well as weekly means of soil temperatures and a monthly summary of precipitation and evaporation for 1891–1898. The summary for 1898 is as follows:

Temperature (degrees F.).—Highest, 88, June 30 and July 26; lowest, —23, January 26; mean for the year, 38.3; highest daily range, 57, June 29; lowest daily range, 3, February 22; mean daily range for the year, 26.4. *Humidity.*—Mean relative for the year, 57.6; lowest relative, 13, July 26 and September 19. *Dew-point.*—Highest, 58°, July 10; lowest, — 21°, December 9; mean for the year, 23.8°. *Terrestrial radiation.*—Highest, 12°, June 11; mean for the year, 3.9°. *Atmospheric pressure* (inches).—Highest, 23.408; lowest, 22.47; mean for the year, 23.020. *Precipitation* (inches).—Highest monthly, 1.88 in June; lowest monthly, traces in September; highest during any single storm, 0.55, August 4; mean for 8 years, 9.95. *Evaporation.*—Total for 6 months (April 15 to October 15), 41.4 in.; greatest monthly, 10.33 in. in June. *Wind.*—Prevailing direction, southwest; greatest velocity, 60 miles per hour; total number of miles traveled during the year (351 days), 99,571; greatest number of miles traveled in 1 month, 11,118, in March; lowest number of miles traveled in 1 month, 4,854, in August; average number of miles for each month, 8,297.6; greatest number of miles in 1 day, 700, October 3; least number of miles in 1 day, 24, August 17; mean daily distance traveled, 283 7; mean hourly distance traveled, 11.8.

Climatic conditions of Oklahoma, J. FIELDS (*Oklahoma Sta. Rpt. 1899, pp. 41–45*).—The general climatic conditions of Oklahoma and their relation to the character of farming pursued are briefly discussed. It is stated that the amount and distribution of rainfall is the most important factor in determining the class of farming which may be profitably undertaken.

"As in the States north and south of Oklahoma, the rule is that the rainfall decreases from east to west and with increased elevation. The evidence is conclusive that eastern Oklahoma has sufficient rainfall so distributed throughout the year as to make the cultivation of most ordinary farm crops reasonably safe, except on high, sloping uplands. It is equally well settled that western Oklahoma is best adapted for grazing purposes; that the soil there had best be left in the natural grass crop, unless irrigation is practicable, or in case of some creek or river bottom land.

"There is a middle section, the boundary lines of which can not be exactly stated, the fitness or unfitness of which for farm crops can not be stated with equal positiveness."

Tables prepared by J. I. Widmeyer show the monthly and annual mean temperatures for 8 years, 1891–1898, at Oklahoma City, and for 4 years, 1895–1898, at Stillwater, Okla., and the total monthly and annual precipitation for periods ranging from 4 to 10 years at 10 places in the Territory.

Meteorological observations at Michigan Agricultural Experiment Station for the year 1897, R. C. KEDZIE (*Michigan Sta. Rpt. 1898, pp. 143–167*).—Tabulated daily and monthly summaries of observations during 1897 on temperature, pressure, precipitation, humidity, cloudiness, wind movement, etc.

The summary for the year is as follows: Mean temperature, 47.01° F.; humidity, 91 per cent; atmospheric pressure (reduced to 32° F.), 29.115 in.; cloudiness, 53 per cent; amount of rain or melted snow, 34.63 in.; snowfall, 39⅝ in.; number of thunderstorms, 16.

Weather report for 1899, G. T. L. (*Agr. Students' Gaz., n. ser., 9 (1900), No. 6, pp. 188, 189*).—A record is given of observations at the Royal Agricultural College, Cirencester, on temperature, rainfall, cloudiness, rainy days, and sunshine.

Observations made at the Blue Hill Meteorological Observatory, Massachusetts, U. S. A., in the years 1897 and 1898, A. L. ROTCH ET AL (*Ann. Astron. Observ. Harvard Col., 42, pt. 2, pp. 131–280*).—This contains the usual reports of meteorological observations made during 1897 and 1898, with an appendix by H. H. Clayton on measurements of cloud heights, velocities, and directions during the "cloud year" of 1896–97.

The weather, R. J. REDDING (*Georgia Sta. Bul. 46, pp. 55–57*).—A brief account of rainfall at Experiment, Ga , during the period from January to November, 1899, inclusive, and mean temperature and rainfall for the period from May to August, inclusive, for each year from 1890 to 1899.

Meteorological observations in the United Kingdom (*Jour. Roy. Agr. Soc. England, 3. ser., 11 (1900), pt. 1, pp. 183, 184*).—A tabular record is given of rainfall, temperature, and bright sunshine for England and Wales during 1899, with average and extreme values for previous years, and of the rainfall of 1899 and of the previous 10 years with the average annual fall for a long period as observed at 38 stations situated in various parts of the United Kingdom.

The campaign against hail in 1899, F. BLASIG (*Atti. Mem. I. R. Soc. Agr. Gorizia, 40 (1900), No. 1–2, pp. 39–51*).

An improvement of the telegraphic weather service, R. BÖRNSTEIN (*Mitt. Deut. Landw. Gesell., 15 (1900), No. 3, pp. 17, 18*).—Discusses the question of the dissemination of forecasts.

WATER—SOILS.

Soil investigations, H. SNYDER (*Minnesota Sta. Bul. 65, pp. 84, figs. 8*).—The work here reported is a continuation of previous investigations (E. S. R., 7, pp. 476, 477, 484) and deals with the chemical and mechanical composition of soils, the available plant food, the characteristic features of Minnesota soils, and the conservation of fertility.

The chemical composition of soils (pp. 1–39).—Analyses of 124 samples of soil (including surface soils and subsoils) from 64 different localities in Minnesota are reported, with descriptions of samples, explanations of terms, and interpretation of results.

The author's main conclusions regarding the 4 most important soil constituents as found in Minnesota soils are as follows:

"*Lime.*—Soils which contain from 0.3 to 0.5 per cent or more of lime and from 0.1 to 0.4 per cent of combined carbon dioxid, and are not strongly charged with alkaline salts, are reasonably well supplied with active lime compounds. . . .

"*Nitrogen.*—Prairie soils of average fertility show high percentages of nitrogen.

> Virgin soil from the Red River Valley has been found with 0.6 per cent of nitrogen. Soils of average fertility contain from 0.15 to 0.20 per cent. With less than 0.07 per cent there is usually a decided deficiency. The availability of the nitrogen depends largely upon the condition of the soil. If there is a good supply of available lime or other basic matter the conditions are favorable for nitrification, and a smaller percentage amount of nitrogen will suffice for crop growth. . . . Average soils with 0.15 per cent of nitrogen and with a good stock of available lime are not apt to be deficient in available nitrogen. . . .
>
> "*Potash.*—Soils that contain 0.4 per cent of potash and 0.4 to 0.5 per cent or more of lime as carbonate or sulphate are as a rule well supplied with available potash. . . .
>
> "*Phosphoric acid.*—A soil that gives an alkaline or neutral reaction and contains 0.15 per cent of phosphorus pentoxid, and is well supplied with organic matter and lime, is amply provided with phosphoric acid, and under such conditions the extensive use of phosphate fertilizers is not required except possibly for special crops."

The mechanical composition of soils (pp. 40–56).—Mechanical analyses of 28 typical Minnesota soils are reported, with descriptions of samples, interpretation of results, and a discussion, with illustrations, of the mineralogical character of the soil particles and the influence of lime, humus, and alkali on the texture of soils.

The available plant food of soils (pp. 57–67).—An account is given under this head of determinations of the sap acidity of a few agricultural plants; a comparison of the Dyer (extraction with 1 per cent citric acid) and Goss (extraction with $\frac{1}{5}$-normal hydrochloric acid) methods for determining available plant food in soils, and experiments in growing wheat in soils extracted with acids. The sap acidity (calculated as citric acid) was found to vary from 0.48 per cent in case of wheat to 1.02 per cent in clover.

The results by the Dyer and Goss methods on 3 soils were as follows:

Available phosphoric acid by Dyer and Goss methods.

	Soil A, very fertile	Soil B, of average fertility.	Soil C, old grain field.
	Per cent.	*Per cent.*	*Per cent.*
Total phosphoric acid	0 230	0.170	0.150
Available phosphoric acid, Dyer method	018	.021	.034
Available phosphoric acid, Goss method	061	.032	.018

The Goss method gave results which were more consistent and more in accord with the known fertility of the soil than Dyer's method.

A sample of soil of average fertility from the station farm (B, referred to above) was extracted with a 1 per cent solution of citric acid for 3 months, a small amount of nitrate of soda added, and wheat grown, normal vigorous plants being produced.

The extraction of the soil with citric acid had failed to remove all of the available phosphoric acid. An examination of the soil before and after extraction and the growth of the wheat gave the following results:

Composition of soil before and after extraction and growth of wheat.

	Original soil.	Soil after extraction and growth of wheat.
	Per cent.	*Per cent.*
Total phosphoric acid	0.17	0.14
Total nitrogen	.28	.20
Humus	8.94	3.81
Humic phosphoric acid	.04	.04
Phosphoric acid of humid acid precipitate	.03	.03
Potash (soluble in hydrochloric acid 1.115 sp. gr.)	.21	.15
Total insoluble matter	83.76	86.40

"The three months' treatment of the soil resulted in the removal of a larger proportional amount of the potash than of the phosphoric acid. Only a slight change in the percentage amounts of humus in the soil before and after the treatment is to be observed, while the phosphoric acid content of the humus and the humic acid precipitate remain unchanged. . . .

"The humic phosphates evidently have a material power to resist the action of acid solvents, but readily yield to alkaline solvents. . . .

"That the citric acid did not change some of the available phosphoric acid of the soil to active forms and that the source of the plant's phosphoric acid was that combined with the organic compounds was proven by direct experiment.

"Two kilograms of soil B was extracted with dilute hydrochloric acid and the humus obtained in the usual way. The humus was dissolved and treated as described in a former bulletin (E. S. R., 7, p. 477). From the kilogram of soil 60 gm. of purified humic material were obtained. The humus was mixed with acid-extracted sand, and a small amount of carbonate of lime and nitrate of soda. When wheat was seeded in this medium, normal plants were produced."

While extraction with $\frac{1}{5}$-normal hydrochloric acid was not directly tested, it is claimed that the results obtained in the experiments with the citric-acid-extracted soil indirectly prove that $\frac{1}{5}$-normal hydrochloric acid would not be effective in removing all of the available phosphoric acid. The author concludes that "both Dyer's and Goss's methods are, without doubt, applicable to certain types of soil, but not to those where a large part of the plant food is in organic forms."

The solubility of the potash of the 3 soils used in the above investigations in $\frac{1}{5}$-normal calcium chlorid, alkaline ammonium chlorid,[1] and 1 per cent citric acid was determined with the following results:

Solubility of soil potash in different solvents.

	Potash soluble in—		
	$\frac{1}{5}$-normal calcium chlorid.	Alkaline ammonium chlorid.	1 per cent citric acid.
	Per cent.	*Per cent.*	*Per cent.*
Soil A, very fertile	0.025	0.07	0.02
Soil B, of average fertility	.015	.02	.01
Soil C, old grain field	.021	.02	.01

---

[1] Prepared by dissolving 10.68 gm. of crystallized ammonium chlorid in 1 liter of $\frac{1}{20}$-normal ammonium hydroxid.

The results were not satisfactory. "Soils known to be deficient in available potash gave higher percentage amounts of soluble potash than soils known to be well supplied with this element."[1]

Characteristic features of Minnesota soils and conservation of fertility (pp. 68–84).—From analyses of 72 samples of surface soils and 52 samples of subsoils the following averages are obtained:

Average composition of Minnesota soils.

	Surface soil.	Subsoil.
	Per cent.	*Per cent.*
Insoluble matter	79.92	82.41
Potash	.43	.40
Soda	.45	.32
Lime	1.29	1.78
Magnesia	.61	.80
Iron and aluminia	7.20	8.32
Phosphoric acid	.20	.17
Sulphuric acid	.10	.06
Carbonic acid	.62	.93
Volatile matter[a]	8 98	5.33
Humus	3.66	....
Nitrogen	.20	.10

[a] The humus and nitrogen form a part of the volatile matter.

"A characteristic feature of nearly all of the soils of the State is a large amount of lime in the form of disintegrated limestone. Only a few soils have been found deficient in lime. . . . Not only is there a large amount of lime, but also a large amount of magnesia. . . . This large amount of basic matter takes an important part, both directly and indirectly, in imparting fertility. . . . The large amount of lime in the soils prevents the formation of acid soils and the plant food from becoming unavailable. . . .

"In the 72 surface soils only 2 were found to contain less than 0.15 per cent of potash and 6 less than 0.20 per cent, while 23 soils contained 0.50 per cent or more, the average amount being 0.43 per cent. The average soil of this State is well supplied with potash.

"In the soils examined about the same amount of soda as of potash was found. . . . In only 3 out of 72 soils was there less than 0.1 per cent of phosphoric acid. . . .

"A close relationship was observed between the amounts of nitrogen and humus of the soil, a high percentage of nitrogen being accompanied by a high percentage of humus. As a rule, there were from 10 to 12 parts of humus to 1 of nitrogen. . . . Many of the rich prairie soils contained originally 0.4 per cent or more of nitrogen—about a third of a pound of nitrogen in a cubic foot of soil. After 20 or 25 years of grain cultivation the nitrogen has been reduced to about 0.25 per cent.'

The influence of continuous grain cropping and summer fallowing on the nitrogen of soils is briefly discussed (see E. S. R., 9, pp. 632, 641). A discussion is also given of the reaction of soils, the amount of plant food in soils, the adaptability of soils to a variety of crops, weeds and fertility, reserve fertility of soils, and the importance of farm rotations and the use of farm manures.

---

[1] See also U. S. Dept. Agr., Division of Chemistry Bul. 56, pp. 53, 54.

"The soils tested have given acid, alkaline, and neutral reactions. Many of the soils that contain high percentages of humus and volatile matter gave slightly acid reactions as well as many that were reasonably well supplied with lime carbonate. . . . But few soils of this State gave decidedly acid reactions."

Analyses of waters, J. FIELDS (*Oklahoma Sta. Rpt. 1899, pp. 70, 71*).—A brief statement of some of the main conclusions from examinations of samples of potable and irrigation waters, the detailed results of which have been reported in bulletins of the station (E. S. R., 11, p. 223).

The problem of impoverished lands (*New York Cornell Sta. Bul. 174, pp. 89–122, figs. 2*).—This is a popular summary, compiled by L. H. Bailey, of information on this subject based on experiments and investigations at the station. The nature of soils, the principles of tillage and underdrainage, and the causes of impoverishment and the means of reclamation of soils are discussed. A series of questions and answers on the general subjects of soils and plant growth is given, with brief directions for making experiments with fertilizers.

Soil temperatures, C. B. RIDGAWAY (*Wyoming Sta. Rpt. 1899, Met. Rpt. 1898, p. 14*).—A table gives weekly means of observations during 1898 at depths of from 3 to 72 in. The means for the year were: 3 in., 42.3° F.; 6 in., 44.3°; 12 in., 44°; 24 in., 44.8°; 36 in., 45.3°; 72 in., 44.5°. The mean temperature of the air (see p. 1017) was 38.3°.

On the method of determining the heat evolved by soils when moistened, A. MITSCHERLICH (*Jour. Landw., 48 (1900), No. 1, pp. 71–80, figs. 2*).—This is a description and account of tests of a simplification and improvement of the method already described (E. S. R., 10, p. 423). It is claimed that by the new method the time required to make a determination is reduced from six to two hours and the errors become almost insignificant.

Productiveness of the soils of Ploti as related to climatic conditions, S. V. SHCHUSEV (*Plodorodie Plotyanskoi va sryazi sa Klimaticheskimi osobennostyami. Odessa, 1900, pp. 54 + III*).—This report is published by the experiment station of Prince Trubetskoi at Ploti. It is printed in Russian, with German title and résumé. In it an account is given of pot experiments with oats and barley grown on the same soil at 3 different places in Russia (Kiev, Ploti, and Novo-Alexandrovsk), and of a comparison of pot and field experiments. Incidentally Bogdanov's method of determining the fertility of soils (E. S. R., 11, p. 130) was studied. Wide variations in both the yield and quality of the crops grown at different places under different climatic conditions were observed.

Humus, A DE VILLÈLE (*Rev. Agr. Réunion, 5 (1899), No. 12, pp. 530–540*).—This is a brief review of the work of various investigators on this subject.

Analysis of Ceres soil, A. J. J. B. SIMONS (*Agr. Jour. Cape of Good Hope, 16 (1900), No. 4, pp. 218, 219*).—Analyses of 4 samples of soil collected in the Ceres Valley, Cape of Good Hope.

Analyses of samples of Siberian soils, A. SEMPOLOWSKI (*Ztschr. Landw. Versuchw. Oester., 3 (1900), pp. 81–122; abs. in Chem. Centbl., 1900, I, No. 15, p. 831*).—The soils examined were from the region of Omsk.

FERTILIZERS.

Fertilizing constituents of feeds recovered in the manure, W. R. PERKINS and E. B. FERRIS (*Mississippi Sta. Bul. 60, pp. 28–32*).—In connection with the feeding experiments referred to on page 1068, determinations were made of the fertilizing constituents in the various feeding stuffs used (Johnson grass, corn-and-cob meal, cotton seed, and

cotton-seed meal), and in the manure from the steers to which they were fed. The composition of the excrement was as follows:

Composition of excrement from steers.

	Nitrogen.	Potash.	Phosphoric acid.
	Per cent.	*Per cent.*	*Per cent.*
Steer No. 1:			
Dung (dry)	1.97	0.58	0.99
Urine	.45	99	.26
Steer No. 2:			
Dung (dry)	2.82	1.08	2.52
Urine	1.04	.87	29
Steer No 3:			
Dung (dry)	2.28	1 12	1.82
Urine	.92	.97	.20

On the average 84.4 per cent of the nitrogen, 92.5 per cent of the potash, and 86.4 per cent of the phosphoric acid of the feed was excreted in the manure. The comparative value of the feed and the manure is shown in the following table:

Comparative value of feeds and manure.

	Cost of feed.	Manurial value of feed.	Manurial value of excrements.	Manurial value of feed recovered in excrements.	Proportion of fertilizing value excreted in dung.	Proportion of fertilizing value excreted in urine.
	Cents.	*Cents*	*Cents.*	*Per cent.*	*Per cent.*	*Per cent.*
Steer No. 1	40 4	15 59	13 85	88.8	58.1	41.9
Steer No 2	39 2	27 21	23 05	84.7	50.0	50.0
Steer No. 3	34 3	22.61	19 23	85.0	56.9	43.1

Plat experiments on the action of lime and magnesia in burnt lime and marl, R. ULBRICHT (*Landw. Vers. Stat., 52 (1899), No. 5–6, pp. 383–430, figs. 7*).—From these experiments, which have extended over a number of years, the following conclusions are drawn:

Yellow lupines were generally injured by applications of lime even with an abundance of potash. The injury was especially marked when the lime contained 40 per cent of magnesia, the latter apparently being poisonous to the plants. Applications of such material also proved injurious to barley, vetch, and radishes (*Raphanus oleiferus*). Experiments with yellow lupines following radishes showed that the injurious effects of heavy liming extended over at least 2 years. Magnesia apparently increased the proportionate yield of grain in the case of lupines, barley, and other plants. Heavy applications of marl reduced the yield of lupines, but to a less extent than the burnt lime. Contrary to the conclusion of Heinrich the variation in the effects of the different calcareous manures was not removed by finely pulverizing them.

Notes on testing soils for application of commercial fertilizers, H. A. WEBER (*Jour. Amer. Chem. Soc., 21 (1899), No. 12, pp. 1095–1099*).—**The author gives various directions regarding the collection of samples**

of soil and describes the method used in making soil tests for farmers at the Ohio State University, as follows:

"Ordinary six-inch tiles are placed into large Wagner pots, which contain enough clean sand so that the top of the tiles will be on a level with the top of the pots. The whole is then filled with sand with the exception of the upper 7 in. of the tiles. The sand is then thoroughly drenched with rain or condensed water. The empty portion of the tiles are next filled to within an inch of the top with the thoroughly mixed sample of soil, the fertilizer is added and incorporated with the upper portion of the soil by stirring, moistened if necessary, 15 seeds of oats, spring barley, spring wheat, or other grain are distributed uniformly over the surface, and then covered with enough of the dry soil to bring the surface of the soil on a level with the top of the tiles. The six-inch tiles, to the depth of 7 in. as described, will contain about 10 lbs. or 5 kg. of soil.

"Five miniature plats are thus prepared for each soil test. If Wagner pots are not available, a box 18 in. deep with an opening in the bottom for drainage, and large enough to hold 5 of the tiles, may be employed. The sand surrounding the tiles is kept moist by adding water once a week.

"The amount and kind of fertilizer to be added to the 5 plats for each test are as follows:

Fertilizers applied in soil test.

	Superphosphate.	Potassium sulphate.	Sodium nitrate.
	Grams.	*Grams.*	*Grams.*
Plat 1 (complete fertilizer)	1.0	0.5	0.5
Plat 2 (complete mineral fertilizer)	1.0	.5	
Plat 3	1.0		.5
Plat 4		.5	.5
Plat 5 (no fertilizer)			

Observations on the growth of the plants during 5 or 6 weeks are considered sufficient to indicate the needs of the soil, and recommendations are made accordingly.

Report of chemist, M. B. HARDIN (*South Carolina Sta. Rpt. 1898, pp. 8–15*).—This is a brief statement of the work of the year in the following lines: The chemistry of the sea-island cotton plant, analyses of soils and crops used in rotation experiments, studies of the changes which the starch of sweet potatoes undergoes during storage, the composition of sugar beets grown in South Carolina, moisture determinations in soils and crops, the preparation of acid phosphates, fertilizer inspection, and examination of water, ores, etc.

"A sample of floats containing 62.17 per cent of phosphate of lime was, without any further grinding, found to yield an acid phosphate containing 15.67 per cent of available phosphoric acid. A sample of dried rock carrying 59.68 per cent of phosphate was found, after grinding so as to pass through a sieve of about 100 meshes to the inch, to give an acid phosphate containing 16.57 per cent of available phosphoric acid; while two samples, one of dried, the other of raw rock, containing respectively 52.98 and 52.74 per cent of phosphate, after passing through the 100-mesh sieve, gave acid phosphates containing respectively 14.29 and 14.84 per cent of available phosphoric acid. The investigation has shown that the character and grade of the acid phosphate from any particular phosphate rock depends largely upon the degree of fineness to which the sample is ground. The sulphuric acid used in the cases referred to was of 50° Baume, and had the temperature of the air. No drier was

> employed. In the case of the floats, the acid phosphate remained slightly damp for several days, becoming gradually hard and dry, but in the other cases the products were perfectly dry and easily handled in from 24 to 48 hours. No free sulphuric acid, or at most but a trace, was found in any of the acid phosphates."

The results of analyses of fertilizers inspected during 1898 have already been reported (E. S. R., 10, p. 624).

> "Of the 314 samples analyzed this year 6 were deficient under the present law, which requires only that the commercial value based upon results of analysis shall not fall 3 per cent below the commercial value based upon guarantee. In addition to these, however, there were 35 samples below guarantee in one or more constituents."

In all of the guaranteed samples (5) of cotton-seed meal the actual percentage of fertilizing constituents exceeded the amounts guaranteed.

Third biennial report of the director of the Missouri Experiment Station on the enforcement of the fertilizer-control law, H. J. WATERS (*Missouri Sta. Rpt. 1898, pp. 70–76*).—This includes an itemized statement of receipts and expenditures of the station on account of the fertilizer control, and tabulated analyses and valuations of 10 samples of fertilizers, representing 4 firms, examined during 1897, and 13 samples, representing 5 firms, examined during 1898, with notes on the trade values of fertilizers and on the amount sold in Missouri.

> "It is estimated that in 1898 the spring sales of fertilizers amounted to approximately 400 tons compared with 300 tons in 1896, consisting chiefly of blood and bone and complete goods, for use on garden truck, strawberries, orchards, potatoes, and corn. The bulk of these fertilizers was purchased by farmers, orchardists, and gardeners in the vicinity of our larger cities.
>
> "The fall sales are estimated to have reached 2,900 tons compared with 1,700 tons for the corresponding period in 1896, and consisted chiefly of raw and steamed bone goods with more or less blood added to bring up the nitrogen content, and in some cases with potash. Most of these fertilizers were applied to wheat.
>
> "Assuming that these fertilizers cost the consumer an average of $25 per ton, the farmers of Missouri invested in 1898 the sum of $82,500 for these materials during the year."

Molasses refuse fertilizer (Melasseschlempedünger), H. SCHMID (*Deut. Landw. Presse, 27 (1900), No. 12, p. 115*).—This material, which has been put on the market under the name of "chilinit," is a product, suited for transportation and for use as a fertilizer, prepared from dilute molasses refuse. It is stated to be of variable composition, but to contain about 3 per cent of nitrogen, 7 to 10 per cent of potash, 15 to 25 per cent of lime, and only a trace of phosphoric acid.

The utilization of stable waste, W. H. BIRCHMORE (*Jour. Soc. Chem. Ind., 19 (1900), No. 2, pp. 118–121*).—Practicable and scientific methods for handling and utilizing stable manure.

On night soil, P. CARLES (*Messager Agr. Midi, 1900, I, No. 2, pp. 70–72*).

Phosphoric acid in agriculture, G. SMETS (*Belg. Hort. et Agr., 12 (1900), No. 4, pp. 53, 54*).

Utilization as a fertilizer of distillery vinasse, V. DEVAUX (*L'Ing. Agr. Gembloux, 10 (1900), No. 9, pp. 573–575*).—It is claimed that this material makes a valuable fertilizer when neutralized with lime and supplemented by applications of phosphatic fertilizers.

The value of blast-furnace dust as a fertilizer, C. Pradel (*Oesterr. Ztschr. Berg u. Hüttenw., 48 (1900), p. 65; abs. in Chem. Ztg., 24 (1900), No. 16, p. 49*).—This material (*Gichtgasstaube*) was found to contain on an average from 4 to 5 per cent of potash and was used with very satisfactory results, especially on oats and barley. Injury from small amounts of sulphocyanid compounds which may be present may be avoided by applying the material from 1 to 2 months before the crop is planted.

The injurious effect of nitrate of soda containing perchlorates, A. Peiermann (*Bul. Sta. Agron. Gembloux, 1900, No. 67, pp. 5-8, pls. 2*).—In experiments with rye grown in glass pots containing 4 kg. of soil, nitrate of soda containing from 0.5 to 10 per cent of potassium perchlorate was applied at the rate of 800 kg. per hectare (714 lbs. per acre). The results indicate that nitrate of soda containing not more than 1 per cent of perchlorates may be safely used.

Fertilizer experiments, F. W. Dafert (*Ztschr. Landw. Versuchw. Oesterr., 3 (1900), pp. 81-122*).—An account is given of the conditions, methods of conducting, and results of demonstration experiments with fertilizers, carried out under the auspices of the Agricultural Society of Vienna in lower Austria during the year 1899. The results are discussed with especial reference to taxation and the economical use of fertilizers. The report contains tables and charts.

Comparative tests of chemical fertilizers, made in 1899 under the auspices of the Vaud Society of Agriculture, E. Chuard and C. Dusserre (*Soc. Vaud. Agr. Bul. No. 137, pp. 574-589*).

The fertilizer resources and the fertilizer industries of Alabama, B. B. Ross (*Tradesman, 43 (1900), No. 2, pp. 51, 52*).—This article discusses briefly the consumption of fertilizers in Alabama and the raw materials which this State furnishes for the manufacture of fertilizers.

Analyses of commercial fertilizers and manurial substances, C. A. Goessmann (*Massachusetts Hatch Sta. Bul. 63, pp. 26*).—This bulletin reports analyses of 272 samples of fertilizing materials, including wood ashes, muriate of potash, sulphate of potash, sulphate of potash and magnesia, bone, dissolved boneblack, acid phosphate, dissolved bone meal, steamed bone meal, spent boneblack, cotton-seed meal, sludge, soot, hen manure, muck, plaster and muck, and complete fertilizers; and of asparagus, velvet bean, and soils.

Analyses of commercial fertilizers, H. J. Wheeler and B. L. Hartwell (*Rhode Island Sta. Bul. 59, pp. 29-35*).—Analyses and valuations of 46 samples of fertilizers collected in Rhode Island during the year 1899.

FIELD CROPS.

Some experiments with subsoiling, B. C. Buffum and W. H. Fairfield (*Wyoming Sta. Bul. 41, pp. 21, figs. 4*).—The results of experiments in subsoiling for cereals and root crops, as a means of conserving the irrigation water applied, are reported for 3 years of work at the home station, 2 years at the Sheridan Substation, and 1 year each at the Wheatland and Sundance substations. One acre of land was used in the different tests, the whole area being plowed 8 in. deep and one-half of it subsoiled to a depth of 16 to 18 in. Wheat, oats, barley, corn, potatoes, sugar beets, and turnips were grown on both halves. Both parts of each plat were irrigated alike.

The yields were not uniform each year. On the whole the yield of wheat was slightly increased by subsoiling and the authors believe that under certain conditions subsoiling for this crop with irrigation might be profitable. Subsoiling was not found profitable, however, with oats, barley, or corn. Root crops made decided gains on the subsoiled plats and the results were better the second year than the first, but the third year after subsoiling the yields were less than those of either the first or second year, owing, probably, to the soil becoming packed. The authors believe that subsoiling may be recommended throughout the State generally for potatoes. The cost of subsoiling in these experiments varied from $3 to $6 per acre.

A comparison was made of the amount of water used in growing crops on subsoiled and nonsubsoiled land.

> "Under our conditions subsoiling has increased the amount of water needed to irrigate the land and apparently is of little value in conserving moisture. However, if no water could be applied by irrigation during the summer, the filling of the reservoir formed by subsoiling with moisture in the winter or spring by rainfall or irrigation would be beneficial."

In an experiment to determine the relative value of 2 light irrigations as compared with 2 light and 1 heavy irrigation for potatoes, the increase in yield, due to the additional heavy irrigation, was over 76 per cent on plowed land and 69 per cent on subsoiled land.

Experiments with crops, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland Tech. Education, Rpt. 7 (1898), pp. 3-38, 77-109*).—Fertilizer experiments were made with swedes, potatoes, oats, clover, hays, and crops in rotation on a number of farms in different counties. The details of the experiments are tabulated and the general results obtained are discussed.

With swedes, barnyard manure has given better results than city sweepings. Applications of from 10 to 12 tons per acre have proved more satisfactory than larger amounts. The addition of commercial fertilizers to barnyard manure has not given sufficiently increased yields with swedes to justify their use. When commercial fertilizers were used without barnyard manure, potash was the most effective element employed, the crop being increased more than threefold by its use in connection with sulphate of ammonia and superphosphate. Lime proved a poor substitute for kainit, and where used in the presence of potash it considerably reduced the yied. Superphosphate has uniformly given the best results of the different phosphatic manures employed, while sulphate of ammonia has proved the cheapest and most effective form of nitrogen.

Barnyard manure increased the potato crop nearly 5 tons per acre, and a still further increase of 1½ tons per acre followed the addition of complete commercial fertilizers to the barnyard manure. The effect of the potash in the complete fertilizers in prolonging the growing period of the potatoes is thought to be the main cause of this increase in yield. Muriate was the most effective of the different forms of potash applied. The use of potash tended to increase the percentage of large tubers.

Oats were grown on poor land after grass. The yields were more than doubled by the addition of complete commercial fertilizers. Bone meal used as a top-dressing for oats gave yields considerably inferior to those obtained by the use of relatively much smaller quantities of a mixture of superphosphate and nitrate of soda or sulphate of ammonia. Its residual effects were also small. The yield of oats increased from 3 bu. per acre without Alinit to 8 bu. per acre when it was applied. The yield on an adjoining plat receiving 125 lbs. of sulphate of ammonia and 200 lbs. of superphosphate was 30 bu. per acre.

The results obtained in experiments with clover lead to the conclusion that with a good "catch" the addition of nitrogenous fertilizers to the crop may prove highly unprofitable. On old hay land nitrate of soda has generally given better results than sulphate of ammonia, and basic slag has proven superior to superphosphate. Complex mixtures of fertilizers have given better results for hay than simpler though more costly mixtures. Applications of ground shells on hay fields have regularly resulted in loss. The importance of applying barnyard manure on hay lands in the fall is strongly emphasized. Cutting and raising the turf to a depth of 4 in. for the purpose of aeration resulted in decreased yields.

Barnyard manure applied to swedes in rotation experiments in 1894 materially increased the oat crop in 1897. The effect on the crop of oats of feeding off part of the preceding turnip crop with sheep getting hay and linseed cake rations was to increase the yield by 13 bu. of grain and 7½ cwt. of straw.

Report on experiments on the manuring of oats, hay, and potatoes, R. P. WRIGHT and J. W. PATERSON (*Glasgow and West of Scotland Tech. Col., Agr. Dept. Rpts., 1898, pp. 7–109, dgm. 1*).—Similar work in 1897 has been previously noted (E. S. R., 11, p. 332) and a synopsis given of the experimental work here reported with potatoes (E. S. R., 11, p. 640).

The fertilizer experiment with oats was conducted on 22 farms and the yields of both grain and straw obtained by the different methods of manuring are tabulated and discussed. From the results obtained, the author concludes that the quantity of superphosphate applied with 100 lbs. of nitrate of soda and 200 lbs. of kainit on oats should not exceed 400 lbs. per acre. Superphosphate proved a more effective source of potash for oats than basic slag applied in like amounts. Sulphate of ammonia proved superior in efficacy to nitrate of soda.

The effect of the fertilizers on the milling value of one of the varieties of oats grown was studied in detail, and these data are reported by A. N. M'Alpine. Scarcely any effect due to the different methods of manuring was apparent.

In the rotation experiments roots were grown on the different plats in 1896, followed by oats in 1897 and hay in 1898. Two methods of manuring have been practiced: (1) Applying all the fertilizers to the root crop and (2) applying the fertilizers to the different crops each year. The latter method has thus far given the best results. Some of the conclusions drawn from this experiment are as follows:

> "Soluble ammoniacal manures (or nitrates) should not be relied upon as a source of nitrogen to the turnip crop unless they are to be repeated. Slow manures, including dissolved bones, all applied to the turnip crop, give an intermediate though certain return throughout. It is unnecessary to reserve part of the bone meal for the oat crop, and, indeed, unprofitable. Basic slag is an uncertain manure on untried soils. It helps, however, the succeeding oat and hay crops, especially increasing the bulk of straw. Single manuring with slow manures can be profitably exchanged for repeated dressings of active fertilizers."

Some of the results obtained with the different fertilizers on hay may be summarized as follows: Basic slag applied alone is not a suitable manure for a rye-grass hay crop. Nitrate of soda is somewhat more effective for hay than sulphate of ammonia. A profitable increase of crop follows the use of either alone or both combined. Phosphatic and potash manures should always be used with these nitrogenous manures on most crops of grasses and clovers. Not less than 100 lbs. of muriate of potash should be applied with each 100 lbs. of nitrate of soda used. The efficacy of barnyard manure for hay is increased by supplementing it with nitrate of soda or sulphate of ammonia.

In experiments conducted on 2 farms to determine the effect of fertilizers on the production of rye-grass seed, it was found that the yield of seed was as certainly increased by the use of manures as was the increase of hay fodder. Basic slag used alone proved the least effective, and nitrate of soda and sulphate of ammonia, used either alone or combined, were the most effective of the commercial fertilizers tested. The addition of mineral fertilizers to the nitrogenous fertilizers still further increased the yield of seed and gave more profitable returns. "Farmyard manure alone, applied in the spring, proved of little value for the production of hay seed." Nitrate of soda and sulphate of ammonia were about equally valuable for the production of either hay or seed.

The relative value of green and yellow colored rye grains for seeding, P. HOLDEFLEISS (*Fühling's Landw. Ztg., 48 (1899), No. 14, pp. 536–540*).—Comments are made upon the experiments of others and those of the author are described at some length.

It appears that green-colored rye grains germinate quicker and have a greater germinative ability than yellow ones. The subsequent development of the plants showed no constant relation to color of grain, although the averages of all the plants from green-colored seed were less developed, the ears appeared later, and the plants were later in flowering. The water requirements of the plants were greater in the case of those from green-colored seed. The total yield of grain and straw was slightly in favor of the use of green-colored seed. The yellow-colored seed produced 89 per cent as much straw as the others, while the grain production from green-colored seed was 82.8 per cent of that from yellow-colored seed. It is stated that the yellow kernels have a greater tendency to transmit their character upon later generations than green ones, and in breeding and improvement experiments with rye this factor is of importance.

Corn culture, R. J. REDDING (*Georgia Sta. Bul. 46, pp. 59-75*).—Cultural, variety, and fertilizer tests with corn are reported. The experiments are in continuation of those previously noted (E. S. R., 11, p. 29). Detailed directions for corn culture, based on the results of ten years' experience in corn growing at the station, are appended.

In 1899, 19 varieties of corn were tested. Unfavorable weather decreased the yield so that scarcely half a crop was harvested. The results of previous variety tests with corn at the station are tabulated and averaged. The varieties Mammoth Yellow, Cocke Prolific, Sanders Improved, Higgins, and Shaw Improved, in the order named, have given the best results of the varieties tested at the station for a number of years.

In experiments to test the value of increasing amounts of fertilizers for corn it was found that on the station soil the yields of shelled corn were not at all increased by doubling or tripling a normal application of 336 lbs. of complete commercial fertilizer per acre. Based on these results the author advises the use of not more than 200 or 300 lbs. of complete commercial fertilizer per acre for corn on high dry uplands.

The residual effects of excessive amounts of nitrogenous fertilizers applied to cotton in 1898 were observed on the corn crop grown on the same ground in 1899. Plats on which cotton seed meal had been used were the only ones which gave increased yields of corn. The general results of the test indicate the nonadvisability of applying excessive amounts of nitrogenous fertilizers to a crop of cotton in expectation that the following crop of corn will be benefited by it.

The results of the experiment to test the relative value of planting corn at different distances in the row were in accord with those of previous years, *i. e.*, planting 4 by 3 ft. gave the best results. In another similar experiment it was found that when 3,630 stalks were grown per acre, the more nearly the spacing between the plants approached a square the better the results.

In a test of different nitrogenous fertilizers furnishing equal amounts of nitrogen, little difference was found whether the source of the nitrogen was nitrate of soda, cotton seed meal, or dried blood. Nitrogen in the form of cotton-seed meal, however, was considerably cheaper than in the other forms.

Harvesting the entire stalk of corn at the usual time in August has been found more economical than letting the stalks stand and harvesting only the ears in October.

Hungarian brome grass (Bromus inermis), T. L. LYON (*Nebraska Sta. Bul. 61, pp. 35-63*).—A botanical description is given of this plant, with an account of culture and pasture experiments at the station and cooperative culture tests throughout the State, and directions for growing the crop, based upon experiments at the station and elsewhere.

In one test at the station, *Bromus inermis* formed a part of a mixture of white, red, and alsike clover, Russian red clover, blue grass, and timothy. By the second year the brome grass had crowded out everything except the red clover. In the spring of 1898, 15 acres were sown in brome grass, on April 2 and April 27. The following season 1.26 tons of hay per acre was cut from a portion of the field, and 177 lbs. or 12.6 bu. of seed per acre was obtained from another portion. A portion kept for pasture was relished by stock. The results from seeding on different dates were practically identical.

A pasture test was made of brome grass for milch cows. Two cows which had been pastured on mixed grasses were placed on separate plats of brome grass aftermath, in one instance 7 days and in the other 10 days, after which they were again pastured on mixed grasses. Separate records of the milk and butter yields of the 2 cows were kept during each period. The results in one instance showed the brome grass to be equal to mixed-grass pasture for milk and butter production, but in the other the results were not so favorable to brome grass. The tests showed, however, that brome grass made a very good quality of pasture.

Chemical analyses were made of brome grass when in full bloom and of rowen when about 12 in. high. The following table shows this data, calculated to water-free material, with analyses of timothy and barley hay for comparison:

Analyses of Bromus inermis and of timothy and prairie hays.

	Bromus inermis		Timothy hay.	Prairie hay.
	Full bloom	Rowen.		
	Per ct	*Per ct*	*Per ct*	*Per ct*
Ash	10.65	13.65	7.39	8.34
Crude fiber	34.71	26.23	34.39	32.40
Crude protein	13.09	18.56	8.84	6.27
Ether extract	2.01	5.69	3.58	2.60
Nitrogen free extract	39.54	35.87	45.80	50.39
Total nitrogen	2.09	2.97	1.42	....
Albuminoid nitrogen	1.70	2.40	1.14	....

Seed of Hungarian brome grass was distributed throughout the State in the spring of 1898 largely to members of the Agricultural Students' Union. Reports from 32 experimenters on the growth during the 2 years have been received. These are incorporated in the bulletin. The conclusions drawn from the work thus far conducted with brome grass are as follows:

"*Bromus inermis* is, all things considered, the most promising cultivated pasture grass for this State that has been tested on the station farm. After once having become established it is unaffected by cold. During periods of extreme drought it lessens growth but does not die. Its advantages over our native grasses are that it becomes green fully a month earlier in the spring and does not dry up in the summer. It also remains green late in the fall. Indications are that it will carry more stock to the acre than most of our prairie pastures. It does not make a good mixture with other grasses, but does well with red clover. As a pasture for dairy cattle it is not equal to a mixture of blue grass and white clover, nor by any means equal to alfalfa as a milk and butter producer, but it is absolutely safe. Chemical analyses of the hay indicate that it is equal to lowland prairie hay for feeding purposes. Tests of the grasses at various points throughout the State, from Pawnee to Dawes County, and from Dundy County, point unmistakably to the fact that it is adapted to a greater range of territory than any other cultivated grass."

Experiments with field and forage crops, F. E. EMERY (*North Carolina Sta. Bul. 168, pp. 421–434, fig. 1*).—This bulletin gives the results of some work in seeding pastures, testing varieties of cotton and wheat, seeding timothy, improving peanuts, and certain notes on the growth at the station of sachaline (*Polygonum sachalinense*) and prickly comfrey (*Symphytum asperrimum*), and on miscellaneous permanent station improvements.

In the experiments with peanuts a lot of Virginia seed was separated into 1-celled, 2-celled, 3-celled, and 4-celled pods and the different lots shelled and planted. The object of the experiment was to see what influence the seed from the different sources would have on the size of the pods of the resulting crop. The results are tabulated for each lot of pods and are remarkably alike. About 5 per cent of each lot grown was 1-celled, 30 per cent 2-celled, 50 per cent 3-celled, and 15 per cent 4-celled. The crop obtained from seed from the 1-celled pods contained a slightly larger percentage of 3-celled pods than any of the other lots and practically as large a percentage of 4-celled pods as the crop obtained from planting seed of 4-celled pods.

Of the 2 varieties of cotton tested, King yielded 186.6 lbs. at ginning and Anson Queen 198.5 lbs.

The results obtained with sachaline were such as to recommend its use for soiling purposes, but not for general farming. Of 16 varieties of wheat tested, Fauntleroy made the best yield, 27.89 bu. per acre in one instance and an average of 20 bu. per acre in a field of 90 acres.

Cooperative range grass and forage plant experiments at Highmore, S. Dak., F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Circ. 21, pp. 10, fig. 1*).—These experiments are being carried on by this Department in cooperation with the South Dakota Agricultural Experiment Station. A large number of grasses and forage plants are being grown to test their adaptability for culture in that region. The plan of the experiment and the results of the first year's work are reported, and notes are given on each of the different grasses and forage plants grown.

"The pressing need of this section of the country is winter feed, either hay, fodder, or pasture. Some of the bunch grasses from the higher altitudes in Wyoming and Montana, such as bunch redtop (*Poa buckleyana*) and smooth bunch grass (*Poa lævigata*), give much promise for winter pasture, while Nevada blue grass (*Poa nevadensis*) and King's fescue (*Festuca kingii*) give promise of both hay and pasture. The frost does not affect them until very late in the season. The favorable growth and behavior of smooth brome grass (*Bromus inermis*) this year, as well as previous experience here and elsewhere in the Northwest with this grass, shows it to be a good hay and pasture grass. On the highest, driest ground of the station it made a good stand and kept green and thrifty during the driest weather. Oregon brome has made a fine showing and deserves a thorough trial on account of its excellent yield of seed and forage, and drought-resistant qualities. The native wheat grasses furnish the larger percentage of the hay in this section and under cultivation and favorable conditions will undoubtedly increase in productiveness.

"Some of the millets introduced from the plains of Russia and some of the varieties of sorghum and fodder corn indicate the possibility of obtaining profitable returns in forage for winter use."

Experiments in range renovation are also under way. "The difference already seen where there has been a summer's rest should be an object lesson to every stockman."

Experiments with forage plants in Ontario, P. B. KENNEDY (*U. S. Dept. Agr., Division of Agrostology Circ. 20, pp. 3*).—A brief report on a portion of the proceedings of the meeting of the Ontario Agricultural and Experimental Union held at Guelph, Ontario, December 6–8, 1899.

In 1899, 23 different experiments were carried on under the direction of the Union by 3,485 experimenters, 739 of whom sent in satisfactory reports. Experiments with grasses showed that the best yield was obtained during the second year's growth. Tall oat grass gave the best yield of the 4 grasses tested. Mammoth clover produced larger amounts of hay per acre than either common red clover, alsike, or alfalfa. Hairy vetch proved the most productive of 3 vetches tested. Medium Green soy beans gave larger yields of both straw and grain than American Coffee Berry or Extra Early Dwarf. Only one crop of soy beans can be grown in Ontario during the season. Of the millets grown, Japanese Panicle heads the list, with 6.4 tons of green hay per acre. The value of crimson clover as a cover crop is pointed out and sustained with figures.

Smooth brome grass, P. B. KENNEDY (*U. S. Dept. Agr., Division of Agrostology Circ. 18, pp. 9, figs. 2*).—Brief historical and descriptive notes on brome grass (*Bromus inermis*), with remarks on methods of seeding in different States, on the value of the plants for pasture and hay, hardiness and drought-resisting powers, and on the distribution of brome-grass seed by this Department. Some results of tests with the grass in 40 States are noted, with brief reports from different growers showing the adaptability of the grass to varying climatic and soil conditions. "It has remarkable drought-resisting qualities and is the most suitable grass yet introduced for the dry regions of the West and Northwest. When once established, it will withstand a temperature of many degrees below zero without being injured."

Grass and forage plant investigations on the Pacific Coast, F. LAMSON-SCRIBNER (*U. S. Dept. Agr., Division of Agrostology Circ. 22, pp. 7*).—This gives a synopsis of the work carried on by this Department to increase the grazing and forage capacity of the ranges east of the Cascades, and also of work on the planting of certain grasses as sand binders. This work has been carried out in cooperation with railroads at Yakima and at Walla Walla, and at various points along the coast and the Columbia River.

In the range experiments about 150 varieties of grass have been tested, some 25 or more showing themselves adapted to the conditions prevailing in the Northwest. Among these common clovers, especially alsike and mammoth red, meadow fescue and tall oat grass have given good results.

"Smooth brome grass has produced the same excellent results here that it has given elsewhere in the Northwest, and gives promise of being to the drier section of this region what the blue grass is to Kentucky and timothy is to the Northern States. Of the more recent introductions the Japanese wheat grass promises to be of great value, particularly for winter pasturage, while the varieties of alfalfa from Turkestan and Northern Africa seem to possess great powers of adaptability to the conditions which prevail in the semiarid regions.

"Some of the best results have been secured from our native grasses. A species of brome, closely related to the rescue grass, has given good yields of seed and forage, and seems likely to prove as valuable for the Pacific coast as rescue grass is for the South. Several of the native wheat grasses show wonderful adaptability to cultivation, and are destined to assume an important place on our list of forage-producing plants. Four of these deserve especial mention, namely, western wheat grass (*Agropyron spicatum*), meadow wheat grass (*A. pseudorepens*), slender wheat grass (*A. tenerum*), and bunch wheat grass (*A. divergens*). The first 3 species are suitable for meadows, and may be grown either with or without irrigation. The bunch wheat grass is a native of the dry uplands, and is likely to prove one of the best grasses for reclaiming the worn-out ranges. The plants thrive under conditions of extreme drought, and afford excellent pasturage for all kinds of stock. . . .

"Another native grass which does well under cultivation and which will undoubtedly prove valuable in reseeding the ranges is blue grama, known in Montana as buffalo grass. . . .

"Of the annual grasses Japanese barnyard millet and black Russian broom-corn millet are most deserving of special mention. Both of these made excellent yields of forage and seed and are of undoubted value to this section."

Some 20 other sorts of grass were successfully grown at Walla Walla and 20 more gave results of sufficient promise to deserve further study and experimentation.

Of the sand-binding grasses, Marram grass, bitter panic grass (*Panicum amarum*), and reed canary grass (*Phalaris arundinacea*) have given promising results. Small sand lyme grass (*Elymus arenicolus*), seaside blue grass (*Poa macrantha*), and Indian millet (*Eriocoma cuspidata*) are other sand-binding grasses of much promise.

The Australia saltbush (*Atriplex semibaccata*) has given the best results of any of the introduced saltbushes, while the white or sweet sage (*Eurotia lanata*) is the most promising of the native series.

In November a study was made at Walla Walla of the behavior of certain grasses and forage crops toward early frosts, the results of which are reported.

Sugar-beet experiments of 1898, G. W. SHAW (*Oregon Sta. Bul. 59, pp. 21, pls. 3*).—This is in part a continuation of work already reported (E. S. R., 10, p. 544). The bulletin sets forth the results obtained in the experiments of 1898, together with observations on the beet-sugar industry now established at La Grande by the erection of a factory. The bulletin also presents the conclusions reached after five years of investigation on the production of beet sugar in Oregon. These conclusions are in part as follows:

> "Three sections of the State are exceptionally well adapted to the industry, viz, Union County, in the vicinity of La Grande; Malheur County, in the vicinity of Ontario and Arcadia; Jackson County, in the vicinity of Medford. Western Oregon is not well adapted to the industry on account of the early fall rains and a soil which is very heavy and sticky, and tenacious to the beet when wet, and it also lacks a cheap lime supply. The Original Kleinwanzlebener and the Elite Kleinwanzlebener have proven themselves well adapted to the conditions in the Grande Ronde Valley, and both have given good results in Jackson County. The former has given the better results in the latter place. Each has given better results in each place than the Vilmorin. In eastern Oregon beets may be left in the ground quite late without serious loss from second growth. Beets for sugar production should not be planted on alkali soils. Beets may be allowed to grow much larger here than in Germany and still hold an excellent percentage of sugar. The hill lands of Jackson County are not well adapted to the industry. The establishment of a sugar factory makes possible a most excellent opportunity for a high development of the dairy industry."

Analyses are given of beet pulp, and notes are given on its use as a food for cattle.

New Mexico sugar beets, A. GOSS and A. M. HOLT (*New Mexico Sta. Bul. 29, pp. 182-212, dgm. 1*).—The work of 1898 was limited to such localities in the State as were supplied with sufficient irrigable land, water, fuel, and limestone as to justify the culture of sugar beets on a commercial scale and the establishment of sugar-beet factories, if it should be found desirable. The results for 1898 demonstrated the advisability of planting in most localities by the first of May, and allowing 5 months for the beets to mature. The average amount of sugar in the juice was 16.5 per cent, with a purity of 82.1 per cent. Beets from Santa Fé County averaged 18.69 per cent of sugar in the juice, with a purity coefficient of 82.1 and an average weight of 1.1 lbs. In San Juan County the data were as follows: Average sugar in the juice, 17.63 per cent; purity, 88.5 per cent; weight of beets, 1.2 lbs. The sugar beets grown at the station were a failure, so far as satisfactory sugar content and purity were concerned.

The Vilmorin and Kleinwanzlebener varieties were planted May 1 and June 1 at three different places in the State, and portions of the beets harvested October 1, November 1, December 1, and January 1 and compared. The results are tabulated. Kleinwanzlebener beets planted May 1 averaged somewhat more than 1 per cent higher in sugar content than the Vilmorin variety planted at the same time, but the Kleinwanzlebener beets planted June 1 averaged between $\frac{1}{4}$ and $\frac{1}{2}$ per cent lower than the Vilmorin variety planted at the same time.

The effect of transplanting beets was tested. "In general the transplanted beets were smaller than the others, and the roots showed a tendency to double up against the beet instead of entering the ground and forming well-formed beets. The principal value of transplanting would be doubtless in filling out the blanks resulting from a poor stand."

The factory conditions of New Mexico are explained and analyses given of 5 of the best well waters of the Missoula Valley, of the Rio Grande River for each month during 1894, and of samples of water from 5 parts of the State where good sugar beets have been grown. Analyses are also given of 10 different samples of limestone from as many different sections of the State.

Instructions for growing sugar beets are reprinted (E. S. R., 10, p. 246), and a bibliography given of recent sugar-beet bulletins.

Wheat-culture experiments, 1898–99, G. E. MORROW and J. H. BONE (*Oklahoma Sta. Rpt. 1899, pp. 33–36*).—The average yield of the 13 varieties of wheat grown at the station during the season was 22.8 bu. per acre. German Emperor and Sibley New Golden each yielded over 27 bu. per acre. Next in order came Fulcaster, Early Ripe, and Red Russian. Turkey gave the lowest yield by nearly 6 bu. of all the varieties grown, 14.7 bu. per acre. The best yielding varieties for the preceding 4 years were Sibley New Golden, 30.7; Missouri Blue Stem, 30.3; Nigger, 29.8; Early Red Clawson, 29.1; Big English, 28.8; and German Emperor, 28.6 bu. per acre.

In the opinion of the authors the results of these tests indicate that wheat can be profitably grown in Oklahoma on the prairie soils. Five pecks of seed has been found a safe quantity to sow per acre, and sowing in September more satisfactory than later seedings.

The influence of neighboring plants on the yield and quality of the crop, STREBEL (*Fuhling's Landw. Ztg., 49 (1900), Nos. 1, pp. 1–6; 2, pp. 41–45; 3, pp. 81–83*).—This records the details of some plat experiments made to determine the effects of planting low-growing and high-growing plants beside each other. Oats, corn, clover, beans, cabbage, and beets were the crops used; and the effects of shade, lodging of the crops, and the withdrawal of water by neighboring plants on the yield and quality of the different crops were the principal features studied.

The chemical change of rye and wheat by mold, R. SCHERPE (*Ztschr. Untersuch. Nahr. u. Genussmtl., 3 (1900), No. 3, pp. 166, 167*).—A controversial article.

The maintenance of soil fertility through the growth of legumes, F. T. SHUTT (*Jour. Agr. and Hort., 3 (1900), No. 21, pp. 485–488*).—The increased results obtained by growing barley, oats, corn, and potatoes after clover are given.

Experience notes upon plat experiments, B. D. HALSTED (*Science, n. ser., 11 (1900), No. 280, pp. 726–732*).—Notes on factors in conducting plat experiments which tend to vitiate results.

Results obtained in the experimental fields of Haute-Marne, M. E. CASSEZ (*Sta. Agron. Nancy Bul. 1, 1899, pp. 37–39*).—Brief report on cultural and fertilizer experiments at the station (1897) with wheat and oats.

Summary of results of experiments with field and orchard crops, J. FIELDS (*Oklahoma Sta. Rpt. 1899, pp. 46–70*).—In this summary are brought together results thus far obtained at the station in variety and cultural tests with wheat, corn, Kafir corn, cotton, castor beans, oats, alfalfa, cowpeas, stock melons, sugar beets, apples, pears, apricots, plums, cherries, peaches, grapes, and nut bearing trees. Notes included in the summary on keeping up fertility and on cultivation and soil moisture have been previously noted (E. S. R., 10, p. 348; 11, p. 433), as have the data for practically all the other crops noted.

Report of the work of the agricultural department, J. D. TOWAR (*Michigan Sta. Rpt. 1898, pp. 121–125*).—A brief review of the work of the year with wheat, oats, corn, and certain forage crops. A plan is given of some fertilizer experiments under way on muck land. Dawson Golden Chaff gave the best yield of wheat recorded during the year, 42.59 bu. per acre. Original seed of Dawson Golden Chaff yielded at the rate of 30.18 bu. per acre.

Winter vetch (*Vicia villosa*) has proven an excellent winter and early spring crop for green manuring, though it seems to be an undesirable food for cattle. Sorghum, Kafir corn, Bedouian corn, pearl millet, and velvet beans also made a good growth at the station.

Rotation tests, S. M. EMERY (*Montana Sta. Bul. 20, pp. 113–118*).—A report is made of the results obtained the first year in a six-year rotation test carried on under actual field conditions with straw and field peas, Canada field peas, barley, sugar beets, oats, red clover, and spring wheat. An account is also given of a test of a land leveler. The use of this instrument is recommended especially on land which has become uneven in the course of tillage.

Alfalfa in eastern Kansas, H. M. COTTRELL, D. H. OTIS, and J. G. HANEY (*Kansas Sta. Bul. 90, pp. 4*).—A popular bulletin calling the attention of farmers in the eastern part of the State to the value of alfalfa as a farm crop. Cultural directions are given, especial attention being paid to methods of seeding alfalfa.

Turkestan alfalfa, N. E. HANSEN (*Amer. Agr.* (*mid. ed.*), *65* (*1900*), *No. 8, p. 232*).—A description of the plant in the United States, with an estimate of its value from a Russian standpoint.

Turkestan alfalfa (*Pacific Rural Press, 59* (*1900*), *No. 3, p. 37*).—Notes on this plant, with the history of its introduction into the United States.

The planting of fodder beets, VON SEELHORST (*Deut. Landw. Presse, 27* (*1900*), *No. 19, pp. 217, 218*).—According to the author's investigations, extending over a period of two years, large plants are better for transplanting than small ones and cutting away the leaves at the time of transplanting to within an inch of the root is a harmful practice.

Cultural worth of American red clover, KIRCHNER (*Deut. Landw. Presse, 27* (*1900*), *No. 15, p. 165*).—A comparison was made at Leipsic of the relative value for hay of American and Bohemian red clover seed. The total yields for each of 3 seasons were in favor of the American seed and but little difference was observable in the food constituents of the 2 clovers. The American clover seed was purchasable in seed markets at a considerably lower price than European grown seed.

Cassava convention (*Florida Agr., 27* (*1900*), *No. 1356, pp. 81, 82*).—Synopsis of papers and discussions presented to the convention at Sanford, Fla.

Divi-divi pods (Cæsalpinia coriaia) (*Agr. Ledger, 1899, No. 10* (*Veg. Prod. ser. No. 51*), *pp. 1–19*).—An article on the cultivation of the plant in India and the value of the pods as a tanning material, with notes on 3 samples obtained from Bengal.

Two new fodder plants for Virginia (*Rural New Yorker, 59* (*1900*), *No. 2613, p. 122, fig. 1*).—Spelt (*Triticum spelta*) and its adaptability to Virginia are especially considered.

Some new grasses from the Southern States, G. V. NASH (*Bul. New York Bot. Gard., 1* (*1900*), *No. 5, pp. 429–436*).—Name, description, and locality of 11 new grasses.

Fertilizer experiments with sulphate of ammonia on meadows, E. KLOEPFER (*Fühling's Landw. Ztg., 49* (*1900*), *No. 3, pp. 107–113, fig. 1*).—The use of 400 kg. of sulphate of ammonia per hectare practically doubled the yield of hay.

Experiences in the application of potash fertilizer on artificial and natural meadows, E. MARRE (*Prog. Agr. et Vit.* (*Éd. L'Est.*), *21* (*1900*), *No. 2, pp. 58–62*).

Culture of mixed oats (*Sta. Agron. Nancy Bul. 1* (*1899*), *p. 39*).—A mixture of 2 choice varieties of oats gave better yields than either of the varieties grown separately.

Potato trials, L. S. SPENCER (*Amer. Gard., 21(1900), No. 270, pp. 128, 129*).—A report is given of tests of 50 varieties in 1899. From the results of the tests, the author recommends the following varieties for general planting: Acme, Early Michigan, Late Norther, State of Maine, Livingston Banner, Livingston Pink, and Gem, ripening in the order named.

The principles and practice of potato culture, L. S. SPENCER (*Amer. Gard., 21 (1900), Nos. 275, pp. 220, 221, fig. 1; 276, pp. 242, 243, fig. 1; 280, p. 314*).—Part 1 of this article deals with the selection of the seed for planting, part 2 with the details of planting and cultivation, and part 3 with harvesting, marketing, and storing.

Potato experiments in Cheshire (*Jour. Hort., 52 (1900), No. 2678, pp. 85, 86*).—From the results of these experiments it is concluded that large potatoes for seed are better than small; sulphate of ammonia is the best form of nitrogen for potatoes. Care must be taken not to use too large amounts of potash.

The degeneration of potatoes and selection at the time of digging, J. BERTHONNEAU (*Semaine Agr., 20 (1900), No. 973, pp. 5, 6*).

Ensiling potatoes (*Queensland Agr. Jour., 6 (1900), No. 2, pp. 82–84*).—A résumé of the work done on the subject in different countries.

Ramie, L. DE BALESTRIER (*Prog. Mexico, 7 (1900), No. 304, pp. 241, 242*).—History and description of this plant in Mexico.

Monograph on rice, G. D'UTRA (*Bol. Inst. Agron. São Paulo, 10 (1899), Nos. 8, pp. 469–513; 9–10, pp, 611–625*).

The culture of rice in Cambodia, A. LECLERC (*Rev. Sci., 4. ser., 13 (1900), Nos. 1, pp. 11–15; 4, pp. 97–105*).

Rice culture in southwest Louisiana, C. U. LAITOR (*Amer. Thresherman, 2 (1900), No. 10, pp. 12–16*).—The method of rice culture successfully followed in southwest Louisiana and southeast Texas is described.

Origination of the Petkus rye, F. v. LOCHOW (*Fühling's Landw. Ztg., 49 (1900), Nos. 1, pp. 28–37, figs. 2; 2, pp. 45–53, figs. 3*).—The details of the author's method of procedure in securing this improved variety of rye are given, together with some of the results obtained.

Notes on sugar-cane experiments, J. B. HARRISON and G. S. JENMAN (*West Indian Bul., 1 (1900), No. 2, pp. 159–172*).—Suggestions as to the use of different manures in cane-growing experiments and in the improvement of varieties.

Experiment in manuring wheat at Coolabah farm, R. W. PEACOCK (*Agr. Gaz. New South Wales, 11 (1900), No. 2, pp. 146–149*).—A comparison of phosphates.

Experimental manuring, A. N. PEARSON (*Jour. Agr. and Ind., South Australia, 3 (1900), No. 7, pp. 562, 563*).—Wheat on fallow land without fertilizers yielded at the rate of 12⅙ bu. per acre. When 20 lbs. of "concentrated" superphosphate per acre was added the yield was increased to 18¼ bu. per acre. The net profit was increased by the use of the superphosphate $2.47 per acre.

Resistance of wheat to frosts, L. THIRY (*Jour. Agr. Prat., 1900, I, No. 7, pp. 235, 236*).—Data as to the effects of frost on 56 varieties of winter wheat.

Wheat for edible pastes in France, J. C. COVERT (*U. S. Consular Rpts., 62 (1900), No. 234, pp. 301, 302*).—Two bushels of Texas-grown wheat of the Nicaragua variety was distributed among different manufacturers of edible pastes in France, who subjected it to careful examination for paste-making purposes. All reports were very favorable.

The world's wheat lands—can we increase their production? H. F. MOORE (*London: The Author, 1899, pp. 8*).—Popular pamphlet dedicated to the Ministers of Agriculture of Canada and the United States, and to the directors of experiment stations in these countries. The future yields of western and northwestern wheat fields are considered.

Conversion through selection of winter Squarehead wheat to summer wheat, A. KIRSCHE (*Deut. Landw. Presse, 27 (1900), No. 15, pp. 166, 167, figs. 4*).—By spring planting winter Squarehead wheat and selection for a number of years a very satisfactory summer variety of wheat has been obtained. Details as to measurements and weighings of the original and selected seed are given, together with natural-size photographs of the new wheat.

The improvement of cereals by cross breeding (*Farmers' Gaz., 59 (1900), No. 8, p 150*).—Methods followed by T. R. Garten and brother in cross breeding wheat at Newton-Le-Willows are briefly noted. *Triticum spelta* has been crossed with an easy shelling cultivated variety of wheat. A cross has been secured with tough heads and tenacious chaff which retains the grain under all atmospheric conditions, even after the wheat becomes dead ripe. The ripe grain is easily obtained by threshing or other mechanical means.

Steam cultivation, J. L. THOMPSON (*Agr. Gaz. New South Wales, 11 (1900), No. 11, pp. 32–35*).—Systems of steam cultivation are discussed and a comparison made of the relative economy of steam, horse, and bullock cultivation.

HORTICULTURE.

Fertilizer and irrigation experiments with popular crops and under glass, A. T. JORDAN (*Amer. Gard., 21 (1900), Nos. 264, p. 22; 265, pp. 38, 39*).—In a paper read before the New Jersey Horticultural Society, at its meeting January 5, the author gives details and results of some field experiments at the New Jersey State Station with asparagus, blackberries, raspberries, currants, gooseberries, strawberries, and certain orchard fruits, in which different fertilizers were used, with and without irrigation. Lettuce and tomatoes were grown on different soils under glass surface and subsurface watering practiced. The experiments have been carried on since 1896, and some of the details have been previously noted (E. S. R., 9, p. 649; 10, p. 433; 11, p. 735). Rows 160 ft. long and divided into 4 equal sections, differently fertilized, were used for each of the different varieties of fruits and vegetables. From 2 to 6 irrigations were required in the different years. Some of the more striking results with the different crops may be noted.

Asparagus.—Six varieties were grown. The first 3 cuttings were taken as representing the early yield.

> "In all cases irrigation has increased the early yield. Combining all lots the increase in favor of irrigation equals 8.4 per cent. In total yields those plats receiving the commercial fertilizers have given, where irrigated, an increase of 9.2 per cent. Where the barnyard manure is used, a decrease occurs under irrigation, equivalent to 4.8 per cent Of the different fertilizers the complete fertilizer alone has given the largest early yield in every case, exceeding any other plat by 17.2 per cent. Relatively, also, the effect of irrigation upon the early yield has been greater where the complete fertilizer has been used alone than upon any other plat. Barnyard manure, where irrigated, has given the smallest increase in the early product. In total yields, the barnyard manure plats gave slightly the larger yields. . . . Relatively, the increase in total yield due to irrigation is greatest on the plat where the nitrate is added. The nitrated plats have, however, given the lowest yields. . . . .
>
> "Palmetto has given the largest yields throughout. It exceeds by 23.6 per cent any other variety in early yield, and by 21.6 per cent in total yields. Donald Elmira is second in yield and Columbian Mammoth White third. Conover Colossal yields the lowest in early cut, with Bar Mammoth lowest in total yield. . . .
>
> "The top growth the first two years was very much larger on the selected crowns than with the same varieties set with commercial roots. However, for the 4 seasons' growth the difference in favor of the selected crowns of Elmira has steadily

decreased and the past season it was small. With Palmetto the difference has grown a little larger each year except the past, when the tops from the selected crowns weighed less than those from the ordinary commercial roots."

Blackberries.—Irrigation increased the early yield of blackberries 39.2 per cent and the total yield 50.2 per cent.

"Relatively, the greatest increase due to irrigation in both early and total yields occurs upon the barnyard-manure plats.

"Where not irrigated, the complete fertilizer with bone and potash gives the largest early yield and also the largest total yield. The barnyard-manure plat gives the lowest returns in both cases. Where irrigated, the plat having the complete fertilizer alone is first in early yield and barnyard manure second. . . .

"In early maturity (yield of first 3 pickings) Early Harvest stands first, with Agawam second Agawam is, however, a most prolific variety, giving a little over ¼ (26.2 per cent) more fruit than Eldorado, the second in yield. Relatively, the effect of irrigation has been greatest with the Eldorado, amounting to 161.6 per cent of that obtained when unirrigated. Agawam is by far the most productive sort when unirrigated, but where irrigated it is but slightly better than Eldorado. These 2 varieties together have given a little over ¾ as much fruit as the other 4 varieties grown."

Raspberries.—Irrigation increased the early yield of raspberries 14.4 per cent and the total yield 19.9 per cent. The plat fertilized with barnyard manure and irrigated gave the largest early yield and also the largest total yield, the increase amounting to a little over ⅓ that obtained from the duplicate plat not irrigated. The plat which received nitrate of soda in connection with complete fertilizer, bone, and potash, gave the lowest yields throughout, though the relative rate of increase due to irrigation was largest on these plats. Only red varieties were tested. Cuthbert gave the largest yield of fruit; Marlborough was a week earlier, and gave the largest relative increase of fruit due to irrigation.

Currants and gooseberries.—Irrigation increased the yield of currants in all cases, the total yield being 25 per cent greater than where no irrigation was used. The barnyard-manure plat gave the lowest yield with irrigation. On the plats not irrigated the best yields were obtained from the complete fertilizer, with the addition of nitrate of soda. With irrigation these plats gave the lowest yields.

There was not much choice of varieties between Red Dutch and Victoria, although Red Dutch had a little larger berry and gave the greater increase due to irrigation. Fay Prolific has thus far failed to give any increase with irrigation.

Irrigation increased the yield of gooseberries in one instance only—on the plat fertilized with the commercial mixture alone. The largest total yields were obtained from plats fertilized with barnyard manure.

Strawberries.—Irrigation increased the strawberry yield as a whole 11 per cent. The best results were obtained from the plat fertilized with complete commercial fertilizers applied at the rate of 500 lbs. per acre. One of the conclusions derived from this experiment is that it is inadvisable to apply nitrate of soda in connection with a fertilizer already rich in nitrogen for strawberries. With low-grade fertilizers, its use is beneficial.

Lettuce.—Lettuce was grown in the greenhouse in a well-prepared forcing soil alone and with fertilizers in a sandy soil and in a clay soil. Different commercial fertilizers were used. The best results were obtained in the unfertilized forcing soil. It is believed that commercial fertilizers are of little use in the forcing house; "A thoroughly enriched sandy loam seems to provide for the wants of the forcing crop in the best possible manner." Subwatering gave an increase in yield on the forcing soil plat of 7.4 per cent. Solid beds were found more satisfactory than benches, as they dried out more slowly and required less watering.

Tomatoes.—Tomatoes were grown under glass, and 1½, 2, 2½, 3 and 3½ sq. ft. of surface given to each plant. The plants given 2½ sq. ft. each gave the largest total yields, but those given 2 sq. ft. each gave the largest total yields relative to the space occupied, and it is believed that this is the best distance for forcing this crop. Subwatering greatly increased the yield of tomatoes. Barnyard manure proved superior to commercial fertilizers as a plant food for this crop. Surface watering was found most suitable for tomatoes grown in pots in which the larger part of the soil was composed of sifted coal ashes. Training to a single stem gave the best results in these experiments. Plats which received no nitrogenous fertilizers gave greatly decreased yields.

An investigation was made of the profitableness of growing the tomato crop in the forcing house. The average gross returns from each square foot of surface has been 65.5 cts. On this basis, the returns for a crop of tomatoes in a house 20 by 100 ft. are estimated at $943.20 and the expense of growing the crop at $278.50, thus leaving a net profit of $664.70 from a little less than $\frac{1}{20}$ of an acre.

Orchard notes, F. S. EARLE (*Alabama College Sta. Bul. 106, pp. 163–176*).—These notes are largely confined to the effects of the unusual cold of February, 1899, on the apples, cherries, figs, grapes, Japanese persimmons, peaches, pears, and plums growing at the station and in different parts of the State. Notes on injurious insects and diseases are given in some instances.

> "On the morning of February 14, the thermometer was below zero in all parts of Alabama. At Auburn it registered —6.5° F., which was 10° lower than at any time in the 30 years during which records have been kept here. In north Alabama the temperature was several degrees lower, while at Mobile and at other points on the coast it was only some 4 or 5° warmer. Here naturally the destruction was greatest. Tender shrubs and trees of all kinds were killed to the ground, the long moss (Tillandsia) on the trees was killed to the ground, and the thickets of saw palmetto were scorched as if by fire. The live oaks and magnolias lost their leaves and even some of the pines were injured. Throughout the State the peach crop and, with a few exceptions, the plum crop was an entire failure."

Apple buds were not swollen at the time of the freeze and were entirely uninjured. The varieties Yellow Transparent for summer and Kinnard Choice for late fall and winter are recommended to be added to the provisional list of apples for Alabama already noted (E. S. R., 10, p. 1041).

Figs throughout the State were killed to the ground by the freeze. Celestial, White Ischia, Brown Turkey, Brunswick, and White Smyrna are considered the best varieties for planting in Alabama. None of the varieties of bunch grapes at the station suffered injury from freezing, but many of the Rotundifolia varieties were seriously frozen, Scuppernong being killed to the ground. Memory was entirely uninjured. Japanese persimmons were killed but sprouted from the crown in some instances. As a result of the freeze, only Persian and North China types of peaches are recommended for central Alabama. The older Keiffer and Le Conte pear trees were uninjured by the cold, though the swollen flower buds were killed. Many younger trees were killed outright. Bartlett and other varieties of European types of pears were dormant at the time of the freeze and escaped uninjured. The injury to plum blossoms was in almost exact proportion to the state of advancement. Only the following varieties bore full crops: Milton, Whitaker, Wooten, Wayland, and Golden Beauty. The Wayland group of plums are recommended for general planting.

In experiments to combat the green aphis of the apple, the most effective remedy was found to be a 25 per cent emulsion made by dissolving ¼ lb. of whale oil soap in 1 qt. of boiling water, emulsifying with 2 qt. of kerosene, and afterwards diluting to 2 gal. The author recommends that this emulsion be applied in a fine mist and only during the middle of bright warm days when the kerosene will evaporate quickly. Injudicious use of this spray or too frequent applications may result in considerable injury to the trees.

As a means of combating apple-leaf rust the author advises the planting of resistant varieties.

Some experiments were made in combating San José scale by the aid of the fungus *Sphærostilbe coccophila* with inconclusive results. Experiments were also made in spraying trees infested with San José scale with 35 and 50 per cent mixtures of kerosene oil. In some instances full strength solutions were used. The results were quite satisfactory except in a few instances where full strength solutions killed the trees. Thirty-five per cent solutions are recommended for combating the scale on apples and 25 per cent solutions on peaches and plums.

Ash analysis of twigs and leaves from apple trees, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 77–81*).—"It was thought that the percentage composition of the ash of bearing twigs of fruit trees would show decided differences from that of so-called water sprouts. To determine the matter, small twigs of 2 seasons' growth from various trees were taken in the spring of the year, when the bearing twigs were covered with fruit buds, more or less opened, and possessing but few and only partially developed leaves, while the nonbearing shoots were straight, thin, and covered wholly with leaf buds or partly opened leaves. The twigs in either case were 8 to 10 in. in length and perhaps ¼ in. thick at the base. In a similar way both kinds of twigs were taken in the fall of the year from a tree which had not borne any fruit that season, and again next spring, when the 2 kinds of twigs differed more markedly in appearance than in the autumn preceding." The following table shows the percentage ash composition of the dry matter of the twigs:

Analyses of apple-tree twigs.

	Calcium oxid.	Potassium oxid.	Phosphoric acid.	Silica.	Magnesium oxid.	Sodium oxid.	Ferric oxid.	Sum.
	Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct*	*Per ct.*	*Per ct*	*Per ct.*
Water sprouts (Fameuse)	1.0290	0.7140	0.3552	0 2156	0.0966	0.0532	0.0070	2.4706
Water sprouts (Bellflower)	1.2717	.7549	.2997	.3613	.1239	.1490	.0316	2.9921
Water sprouts (Jennetin) fertilized with wood ashes	.6132	1.2782	.2198	.2450	.0591	.0896	.0217	2.5266
Average	.9713	.9157	.2916	.2740	.9932	.0973	.0201	2.6631
Fruit twigs (Fameuse)	2.1417	1.0455	.5410	.2538	.1207	.0730	.0124	4.8831
Fruit twigs (Bellflower)	2.3262	1.0935	.5432	.4395	.1509	.0754	.0262	4.6550
Fruit twigs (Jennetin) fertilized with wood ashes	2.3912	.7228	.3111	.6222	.1080	.1241	.0256	4.3023
Average	2.2864	.9539	.4651	.4385	.1265	.0908	.0231	4.3818
Twigs with fruit set (Jennetin) fertilized with wood ashes	2.0702	1.0364	.3819	.2645	.1288	.0399	.0228	3.9946
Twigs that had died of blight from same tree	2.3830	1.0925	.4428	.2866	.2054	.1870	.0332	4.4397

"It will be seen that while the percentages of the different components in the ash do not show striking differences for the two groups, excepting in lime and potash, yet, when calculated for dry matter in twigs, the results are obviously pregnant with meaning. Surely the much larger absolute amount of lime, phosphoric acid, and potash in the bearing twigs must be either the cause or the condition of their bearing. . . .

"The legitimate deduction from the foregoing facts would seem to be that the effect of fertilizing fruit trees can not possibly manifest itself the same year in an increased fruit crop, but appears of a certainty the year after, and that fruit growers, in valuing fertilizers, must bear this in mind to arrive at correct conclusions."

Analyses of ashes from apple peelings and leaves from trees fertilized and not fertilized with iron sulphate, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 82, 83*).—The leaves and peelings taken for analysis in this experiment were obtained from Ben Davis trees, some fertilized and others not fertilized with iron sulphate. The fruits of the fertilized and not fertilized trees showed marked differences in appearance, the greater depth of color being in favor of the apples from the trees fertilized with the iron sulphate. The fruit was harvested at the usual time and the peelings and leaves carefully dried without being permitted to come in contact with any iron or steel instrument. The following table shows the results of the analyses of 100 gm. of water-free substance in each instance:

Analyses of ashes of apple peelings and leaves.

	Fine ash.	Silica.		Iron.	
	Grams.	Grams	Per cent.	Gram.	Per cent.
Fertilized with iron sulphate:					
Peelings	....	1.769	4.70	0.0131	0.74
Leaves	....	10.490	6.06	.0597	.57
Not fertilized with iron sulphate:					
Peelings	1.984	.220	11.09	.035	1.77
Leaves	12.641	.431	3.41	.075	.59

"The result as regards the quantity of iron is the reverse of what was expected, and if affirmed by subsequent trials can not be the direct cause of influencing the color of fruit. Indirectly, by perhaps stimulating the development of certain definite constituents, it might exercise an effect, as was plainly discernible in this trial."

Effect of spring frosts on the peach crop, with cultural notes on the peach in New Mexico, F. GARCIA (*New Mexico Sta. Bul. 30, pp. 215-251*).—The author states that the most serious drawback to the successful culture of the peach in New Mexico is the late spring frosts, which are certain to occur after the trees have started to bloom and which often destroy the whole crop. A very large percentage of the blooms and fruit buds are killed every spring by the frosts. In order to determine the more resistant sorts and the varieties best suited for culture in New Mexico, a careful record extending over 4 seasons was kept of the date of blooming, fruiting habits, and ripening period of 147 different varieties of peaches growing in the station orchard. The daily temperature of the winter and spring months for each season (1895-1898) was kept and a study made of the effect of frosts on the different varieties of peaches after they come into blossom.

The different varieties have been arranged in groups, according to the fruiting habits of each. Twenty-two of the varieties grown ripened their fruit in June and July, 38 in August, 16 in September, and 3 in October and November. Eleven varieties have fruited 2 seasons during the whole test, and 57 sorts have not fruited at all. Usually observations have been made upon 4 trees of each variety, although in some instances only 1 tree was available. Tables showing date of bloom, number of days of frost, minimum temperature after bloom, and date of ripening during the different seasons are given for each group, and the data commented upon at length.

The bulletin is summarized in part as follows:

"No variety that has been tested in the college orchard blooms late enough to escape all the freezing weather, although many kinds usually escape the most severe frosts.

"The date of full bloom in the several varieties of the peach varies from year to year, depending on the character of the season.

"The early peaches as a rule bloom later than the late varieties, thus escaping many days of varied freezing weather, and insuring a crop unless killed by severe frosts occurring some time after the fruit is set.

"Belated buds, being comparatively undeveloped when the main crop of flowers are open, frequently escape frosts that kill the full blossoms, thus setting at least a partial crop.

"Many varieties, especially the early kinds like Alexander, that fail in other States because of fungus diseases, do well in New Mexico, and some of them are leading commercial sorts."

The varieties which have best withstood frosts during the whole period and which are recommended as suitable for commercial orchards are Alexander, Arkansas Traveler, Waterloo, Gov. Garland, S. G. French, Boyle Early, Hyne Surprise, Family Favorite, and Muir. These same varieties are recommended for home use, and in addition George IV, Sargent, Early Silver, Hoover Heath. The varieties which have failed 1 or 2 years at the station, but on the whole have proved profitable, are Early Crawford, June Rose, Cother, Sallie Worrell, Hill Chili, Piquett Late, Chinese Cling, and Bequett Free. All but the last 2 of these are suitable for planting in commercial orchards.

Relative to the culture of peaches in New Mexico, it may be noted that irrigation is necessary for this industry. The selection of sites for peach trees, choice of soil, methods of irrigation for peaches, pruning and thinning commercial peach orchards, and the insects and diseases affecting peaches are briefly discussed.

The bulletin contains brief introductory remarks on peach culture in New Mexico by C. A. Keffer.

Fourth report on Japanese plums, L. H. BAILEY (*New York Cornell Sta. Bul. 175, pp. 123–151, figs. 18*).—This is a continuation of work already reported (E. S. R., 9, p. 1053). Notes are given on varieties of Japanese plums as taken on the station grounds during the season of 1899. The varieties recommended as most valuable for general uses and conditions and worthy of general planting are Engre, Lutts, Red June, Abundance, Burbank, Chabot, and Satsuma, enumerated in the order in which they ripened at Ithaca in 1899. Other varieties of secondary value, or those which must be further tested before they can be confidently recommended, are Berger, Kerr, Ogon, Georgeson, Hunn, Hale, and Wickson, named also in the order in which they ripened at Ithaca in 1899.

As a result of his observations for a series of years, the author believes that many of the great differences in opinion respecting the merits of individual varieties and the wide discrepancy in descriptions of them that are frequently made are due to the fact that the same tree may bear unlike fruit in different years.

Prunes, J. A. BALMER (*Washington Sta. Bul. 38, pp. 1–36, figs. 11*).—This bulletin is designed to supply information as to the best methods of preparing prunes for market. Cultural methods in most common use locally are briefly discussed, notes are given on the Italian, French, and Silver varieties of prunes, the merits of each are presented, and the details of preparing the fruit for market are set forth with considerable fullness. The processes treated of are evaporation, grading, dipping, packing, and sweating, the paragraphs on evaporation and grading especially including accounts of a number of methods and kinds of apparatus in use. A number of the pieces of apparatus are figured.

It is stated that prunes have a relatively high feeding value for hogs. Fed alone, they do not form a well-balanced ration, but with a little barley or pea meal added, it is said, hogs will grow and fatten well.

Strawberries, S. M. EMERY (*Montana Sta. Bul. 20, pp. 104–109, chart 1*).—Variety tests and experiments in pollination of strawberries are reported. An experiment was made with Crescent seedling strawberry plants, the object of which was to determine the distance at which pistillate and staminate plants should be set to secure the best results in pollination. The arrangement of varieties and the yield of each plant in the experiment are shown in a chart. Not a single uncovered plant failed to mature some fruit, although some of them were from 20 to 27½ feet distant from any staminate plants. At the same time a second experiment was made with a part of the plants just referred to, the object of which was to determine the extent of the agency of insects in pollenizing strawberry blossoms. A part of the plants were covered with cheese-cloth netting, the meshes of which were $\frac{1}{16}$ of an inch in diameter. Those plants which remained covered throughout the experiment failed to produce a single good berry although there were a few very imperfect ones. It was observed in the course of this experiment that much the largest yield of fruit was obtained from those plants immediately adjacent to those covered with the cheese cloth. "It was as if pollen-laden insects had been attracted by the white covering of cheese cloth and had traveled over it to sides or ends, and failing to get entrance to the protected blooms underneath had moved to the plants the nearest thereto."

The chemical composition of certain small fruits, A. D. SELBY (*Ohio State Hort. Soc. Rpt. 1898, pp. 150–154*).—The author has made determinations of the percentages of water, solid material (both soluble and insoluble), seeds, acid, sugar, pectins, fiber, and ash of 11 varieties of strawberries, 7 of raspberries (1 black, 1 purple, and 5 red varieties), 4 of currants, 2 of blackberries, and 3 each of gooseberries and cherries. Fruit of the different sorts was gathered and analyzed on different dates during the ripening period of each. The data for each variety are tabulated. The following table summarizes the analyses:

Average analyses of small fruits and cherries.

	Water.	Seeds.	Crude fiber.	Protein.	Ash of seeds.	Ash, excluding seeds	Soluble solids.	Free acids.	Reducing sugars.	Pectins.	Ratio of acids to sugar.
	Per ct.	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*	*Per ct.*
Strawberries	92.55	0.93	0.31	0.61	0.03	......	4.48	1.01	3.03	0.62	0.23
Black raspberries	80.86	6.26	.21	1.50	.09	0.55	9.83	1.20	6.44	.97	.19
Red raspberries	83.59	2.20	.23	1.20	.05	.45	1.45	1.62	8.20	1.40	.20
Blackberries	85.53	3.56	.38	1.26	.10	.29	8.87	0.91	7.57	......	.13
Red currants	85.55	1.58	.41	1.21	.03	.57	10.31	2.73	6.82	1.17	.40
Gooseberries	86.44	1.41	.43	.74	.05	.28	12.23	1.61	4.06	.45	.40
Sour cherries	81.72	5.22	......	1.43	......	......	10.74	1.47	7.38	1.09	.20

"These samples were chiefly taken in good, fair weather. . . . Much less acid and sugar and, therefore, less water-soluble solids and nutritive matter would be found after rainy weather and scant sunshine."

Report of the horticulturist, L. R. TAFT (*Michigan Sta. Rpt. 1898, pp. 126–133*).—This is a brief summary of the work of the department during the year, showing the different lines of experiments undertaken and the progress made. Crimson clover used as a cover crop in orchards has given the best results when seeded July 1. Oats have proven well adapted for use as an orchard cover crop on heavy clay soils. The results in successful spraying experiments against the peach leaf-curl are reported and are noted elsewhere in this issue (p. 1059). Wood ashes have given good results on lawns when applied at the rate of 50 bushels per acre. The effect of wood ashes and ground bones combined was prominently visible on lawns throughout the whole season.

Report of the horticulturist, J. F. C. DU PRE (*South Carolina Sta. Rpt. 1898, pp. 22–36*).—Brief notes on the asparagus, beans, Lima beans, beets, table beets, stock beets, sugar beets, Brussels sprouts, carrots. cabbages, cauliflower, celery, cucumbers, eggplants, cantaloupes, lettuce, watermelons, onions, potatoes, English peas, strawberries, apples, pears, peaches, plums, Japanese persimmons, and other fruits and nuts grown at the station during the season. Data and descriptive notes as to yields and best varieties are given in some instances, and mention made of the more prevalent insects and diseases of fruits.

Asparagus culture in the South, W. F. MASSEY (*Florida Agr., 27 (1900), No. 19, pp. 202, 203*).—The profitability of this crop is discussed and detailed directions given for its culture and fertilization.

Bur, or Globe, artichokes, W. T. SWINGLE and D. G. FAIRCHILD (*U. S. Dept. Agr., Division of Botany Circ. 22, pp. 6, fig. 1*).—A brief description of the artichoke, *Cynara scolymus*, with notes on methods of culture in Europe and in Louisiana. Methods of cooking are suggested.

Manuring field cucurbits, H. KOCH (*Deut. Landw. Presse, 27 (1900), Nos. 22, p. 253; 24, p. 278*).

Yams in the West Indies, D. G. FAIRCHILD (*U. S. Dept. Agr., Division of Botany Circ. 21, pp. 4, fig. 1*).—The varieties of yams (*Dioscorea* spp.) in Jamaica and Barbados and methods of yam culture observed in these places are given, with some suggestions as to their adaptability to the subtropical agriculture of the United States.

Horse-radish culture in Bohemia, D. G. FAIRCHILD (*U. S. Dept. Agr., Division of Botany Circ. 20, pp. 3, figs. 2*).—Brief descriptive and cultural notes on a variety of horse-radish known in Germany and Austria as "Malner" or "Maliner Kren" which has been imported for distribution.

Some Chinese vegetables (*Sci. Amer., 83 (1900), No. 14, p. 211*).—A description of some of the vegetables sold in the Chinese quarters of San Francisco (E. S. R., 11, p. 777).

Distribution of seeds and plants, E. J. WICKSON (*California Sta. Seed Bul., 1899–1900, pp. 4*).—A list is given of the plants and seeds available for distribution through the station for the coming season. The usual condition of a small payment for seeds is retained, and the limited quantity of many varieties is mentioned in order to insure early application. The plants offered this season are new varieties of European strawberries; trees and shrubs, mostly exotic; resistant grapevines; plants for green manuring; forage plants; cereals; and promising varieties of garden plants.

Edible fungi, A. NYS (*Belg. Hort. et Agr., 12 (1900), No. 4, pp. 51, 52*).—A popular article on mushroom culture, uses, etc.

Plant breeding by bud selection, A. S. HITCHCOCK (*Amer. Gard., 21 (1900), No. 266, p. 59*).

Stringfellow method of planting an orchard, H. M. STRINGFELLOW (*Nat. Nurseryman, 8 (1900), No. 3, p. 25*).—The author describes his method for setting peach, pear, and apple trees in sod.

Fruit-tree pruning—No. 9, G. QUINN (*Jour. Agr. and Ind., South Australia, 3 (1900), No. 7, pp. 589–603, figs. 17*).—The principles of pruning evergreen fruits are discussed and detailed, illustrated directions given for the culture and pruning of lemons, oranges, and loquats.

Fruit growing under irrigation, W. J. ALLEN (*Agr. Gaz. New South Wales, [illegible] (1899), No. 12, pp. 1268-1274, pls. 3*).—Popular articles largely taken from California sources.

Grafting oranges on Bitter Seville stocks (*Agr. Jour. Cape Good Hope, 16 (1900), No. 5, pp. 305-310*).—Suggestions regarding the use of Bitter Seville as stocks. Its use is especially recommended as a resistant stock against root rot.

Orchard trees, S. M. EMERY (*Montana Sta. Bul. 20, pp. 98-104*).—Observations are reported on the hardiness at the station of a large number of varieties of orchard fruits set in 1895, and a list of the apples, crab apples, pears, cherries, plums, and prunes that have thus far proved hardy is given. Brief popular notes are given on the leaf blight of apples, which, it is stated, has not as yet been observed in Montana.

The effects of alfalfa and grass on the growth of young orchard trees (*Hessische Landw. Ztschr., 70 (1900), No. 7, pp. 78, 79, fig. 1*).—Alfalfa seriously retarded the growth of young apple trees as compared with trees grown on land in cultivated crops and wheat.

Classification of the peach (*Amer. Gard., 21 (1900), No. 269, pp. 116, 117*).—Extracts from an article delivered by R. H. Price before the Natural History Society of the Agricultural and Mechanical College of Texas.

Propagation of native plums, F. CRANEFIELD (*Rural New Yorker, 59 (1900), No. 2612, p. 103*).—Crown grafting year-old trees, top grafting older trees, and intensive and thicket culture of native plums are discussed.

Persimmons, M. L. HENRY (*Jour. Soc. Nat. Hort. France, 4 (1900), No. 1, pp. 132-138, fig. 1*).—Cultural directions, with notes, on the flowering habits and methods of pruning Japanese persimmons (*Diospyros kaki*).

Instructions in the culture and uses of cacao, G. D'UTRA (*Bol. Inst. Agron. São Paulo, 10 (1899), No. 9-10, pp. 539-581*).—A description of the methods of culture and manufacture in Brazil, with an analysis of the seeds.

Coffee culture in Queensland—No. 2, H. NEWPORT (*Queensland Agr. Jour., 6 (1900), No. 2, pp. 120-125, figs. 2*).—Details are given regarding the nursery management of coffee trees.

Tea, its culture and manufacture, V. BOUTILLY (*Le thé, sa culture et sa manipulation. Paris: G. Carré and C. Naud, 1898, pp. 108, figs. 18*).—The origin, botany, and production of tea are considered, together with methods of culture and manufacture followed in Ceylon and the adaptation of those methods in the French colonies.

The manuring of tea (*Planting Opinion, 5 (1900), No. 14, pp. 237, 238*).—Results obtained in manuring tea with 9 different combinations of commercial fertilizers are reported and an analysis given of the soil on which the tea grew. No conclusions are drawn from the tests.

Vanilla and other cultures in Réunion, C. W. BENNETT (*Bul. Bot. Dept. Jamaica, n. ser., 7 (1900), No. 1, pp. 8-14*).—Special attention is given in this article to the drying of vanilla by the use of chlorid of calcium.

Culture of vanilla in Mexico, H. LEMCKE (*Tropenpflanzer, 4 (1900), No. 3, pp 130-139*).

Vanilla (*Garden, 57 (1900), No. 1469, p. 35, fig. 1*).—Methods of greenhouse culture are given. The author states that from his experience it is not a profitable plant to grow under glass.

Nutmeg growing in its native home (*Jour. Jamaica Agr. Soc., 4 (1900), No. 4, pp. 208-210*).—Gives methods of growing and curing the nutmeg in the Dutch East Indies.

Studies on the hop, F. CHODOUNSKY (*České Listy Hospodářské, 8 (1900), No. 1, pp. 8-15, figs. 7*).

Currants for market and the home garden, T. J. DWYER (*Amer. Gard., 21 (1900), No. 274, pp. 203, 204*).—General cultural directions with descriptions of 5 desirable market varieties and 2 varieties for the home garden.

Pot-grown strawberries for the home garden, T. J. DWYER (*Amer. Gard., 21 (1900), No. 275, pp. 221, 222*).—Suggestions regarding the growing of strawberries in pots for transplanting in the home garden with descriptive notes on 6 varieties well suited for this purpose.

Influence of different cuttings on the quality of wines, G. HERON (*Prog. Agr. et Vit., 16 (1899), No. 37, pp. 314-320*).

Experience with the English walnut, N. POMEROY (*Amer. Gard., 21 (1900), No. 275, p. 223, fig. 1*).—The author reports growing these nuts in Niagara County, New York. The trees have withstood a temperature of —18° F.

Root grafting the walnut (*Pacific Rural Press, 59 (1900), No. 12, p. 177, figs. 3*).

Grafting the walnut (*Pacific Rural Press, 59 (1900), No. 11, p. 161, figs. 5*).—A description of methods of grafting the English and the black walnut.

India rubber cultivation (*Planting Opinion, 5 (1900), No. 4, pp. 64, 65*).—This article discusses the culture and production of rubber from different species of rubber trees and states that "experiments are now being carried on in London and Trinidad to secure rubber from year-old plants of the *Castilloa elastica*. . . . It has been found that seeds sown broadcast over a prepared field will yield an abundant crop of young trees which at about one year old can be cut and sent to a factory where, with ordinary machinery, 8 per cent of fine rubber can be extracted from the young shoots. . . . This young tree crop, at present prices, would return an estimated profit of $200 to $400 per acre."

Rubber trees and their culture, H. LECOMTE (*Les arbres a gutta-percha leur culture. Paris: G. Carré and C. Naud, 1899, pp. 95, figs. 7, map 1*).—This work treats of the species of plants producing rubber, of the collection and manipulation of sap, production and commerce in rubber, and of the acclimatization of plants in the Antilles and Guiana.

Culture of rubber, G. D'UTRA (*Bol. Inst. Agron São Paulo, 10 (1899), No. 8, pp. 514-536*).—A description is given of species and varieties of plants producing rubber, with notes on the establishment and management of a rubber grove and on the collection and handling of the sap. A list of the substances found to be useful in coagulating the milk of sap is included.

India rubber in South America (*Sci. Amer., 82 (1900), No. 8, p. 122*).—Abstract of report to the French Government by M. Poisson.

The tapping of the rubber tree, E. HENRICI (*Tropenpflanzer, 4 (1900), No. 2, pp. 79, 80*).—Results of trials of tapping relative to flow of sap and effect on tree.

A gutta-percha plant susceptible of being cultivated in temperate climate, DYBOWSKI and G. FRON (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 15, pp. 158-160*).—An account is given of the successful cultivation in Europe of *Eucomia ulmoides*, a plant belonging to the Euphorbiaceæ. The plant is described at some length, and the method of separating the gutta-percha and the amount obtained. The plant originally comes from the north of China, and it is thought that its cultivation can be successfully carried on in regions possessing similar climatic conditions.

American-grown bulbs (*Florists' Exchange, 12 (1900), No. 18, p. 476*).—Comments by Andreas Simon, of Chicago, on growing bulbs, especially in the Puget Sound region.

Sweet peas in Canada, S. P. (*Amer. Florist, 15 (1900), No. 617, pp. 1041-1043*).—Light clay loam is considered the best soil for sweet peas. On poor soil, sandy soil, or heavy clay, the trench system of culture is recommended. Descriptive notes are given on the growth of 35 varieties.

Flower farms of California, S. M. HALL (*Land of Sunshine, 12 (1900), No. 5, pp. 280-290, figs. 9*).

The flower gardens of Japan, F. W. BURBRIDGE (*Garden, 57 (1900), No. 1484, pp. 304-306, figs. 2*).

FORESTRY.

Report upon the forestry investigations of the U. S. Department of Agriculture, 1877-1898, B. E. FERNOW (*U. S. House Representatives, 55. Cong., 3. Sess., Doc. 181, pp. 401, figs. 105, pls. 32*).—This is a special report "upon the forestry investigations and work of the Department of Agriculture, showing the results obtained and the practical utility of the investigations," prepared in accordance with a provision in the act of Congress making appropriations for the Department of Agriculture for the fiscal year ended June 30, 1899. The author treats the subject in 3 parts: (1) A brief historical sketch of the administrative features of the Division of Forestry, with the reasons for its establishment; (2) the work done by the division, and (3) a résumé of the status of the forestry movement in the United States and the relation which the Division has had to it.

The principal part of the report is contained in an appendix on "Forests and Forestry in the United States," in which is comprised a summary account of forestry conditions in the country, geographic distribution and classification of forests, and a list of 100 trees of the United States important in forestry; biological studies on the Southern pines (E. S. R., 8, p. 602); a description of the various kinds of wood and their present application in the arts (E. S. R., 7, p. 774); a detailed study of the structure of the wood of 5 Southern pines (E. S. R., 8, p. 602); a discussion of the economic aspects of the forest resources of the United States; an illustration of forest conditions in the lumbering regions of the Northwest, based on a survey of the forestry conditions in Wisconsin and a study of the stages brought about in the course of exploitation (E. S. R., 10, p. 51); a detailed study of the naval-store industry in the United States, reprinted mostly from the Annual Report of the Division for 1892; notes on the origin and development of the forestry movement in the United States, including accounts of the forestry legislation in various States and a list of bills relative to forestry introduced into Congress; a discussion of the forest policies of European nations; a discussion of the forest conditions and methods of forest management in Germany, with a brief account of forest management in British India; text book presentations of the principles of sylviculture and of forest economy; forest influences (E. S. R., 5, p. 94); a summary account of the timber-physics work of the Division (E. S. R., 3, p. 729, and 5, p. 96); and a very brief summary of the results of the Division's investigations on metal ties for railways (E. S. R., 7, p. 164). In several cases the papers are reprints or abstracts of former publications of the Division of Forestry.

The thinning and pruning of forest areas, C. E. CURTIS (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 4, pp. 617-625, figs. 4*).—An account is given of the management of a young oak plantation in the north of Ireland. The plantation is a rather extensive one and is about

30 years old. The oaks were planted at 12 ft. distances, with larch, spruce, silver fir, and Scotch and Austrian pines as nurse trees. The larches were seriously attacked with canker and have all been removed. The other trees have made satisfactory growth. The present stand shows oaks at the rate of 300 to the acre, with about 200 nurse trees. The oak trees have been pruned twice, each time between the months of November and March. The branches did not exceed 3½ in. in diameter and were cut upward close to the trunk, leaving a smooth surface, which has healed readily. In this way clean trunks to 12 ft. have been secured, and it is intended to prune further until clean stems of over 20 ft. are secured, after which the natural pruning will be depended upon.

The thinning of the plantation has been gradual, small thinnings being made now and then, and has been found most beneficial.

Lightning and its effect on trees, F. J. Brodie (*Jour. Roy. Agr. Soc. England, 3. ser., 10 (1899), pt. 4, pp. 608–617, figs. 2*).—On account of the recent damage to beech trees at a number of places, an investigation was made on the effect of lightning on trees. It is stated that the greater number of the injured trees presented the appearance of dead tracts of bark and wood from 8 to 12 in. wide, running a long way down the stem of the tree. The bark had begun to crack and fall off, exposing the hard, dead wood below, which was cracked with numerous shallow fissures. Along the edges of the injured tracts the uninjured bark and stem were developing a healthy and vigorous callus, which was gradually repairing the injury.

Original and compiled notes are given on the liability of different varieties of trees to lightning, considerable quotations being made from a report of the Weather Bureau of this Department (E. S. R., 8, p. 34; 11, p. 322).

Forest department, S. M. Emery (*Montana Sta. Bul. 20, pp. 96–98*).—A report is made upon a test of a number of species of forest trees, begun at the station in 1895. The species which have thus far done best are white birch, cottonwood, bur oak, European larch, Scotch pine, Austrian pine, red cedar, and Colorado blue spruce. Brief economic notes are given on the narrow-leaf cottonwood (*Populus angustifolia*), and the broad-leaf cottonwood (*P. balsamifera*).

Shade trees, J. Fields (*Oklahoma Sta. Rpt. 1899, pp. 78–80, pl. 1*).—Notes are given on a number of shade trees which have been planted and are under investigation by the station. A report is given of the condition in June, 1899, of the forest trees grown on the station grounds in cooperation with the Division of Forestry of this Department. A summary is also given of the degree of hardiness of a number of the more prominent varieties.

Observations on the forests of eastern Pandoland, T. R. Rim (*Agr. Jour. Cape Good Hope, 16 (1900), Nos. 1, pp. 21–42; 2, pp. 104–115*).—Notes are given on the general characteristics of the forests of this region. The principal species are described and the distribution, economic characteristics, and common names are given. It appears from remarks concerning the vertical distribution of the species, that 2 species do not extend to the coast, 8 are confined to the coast region below 500 ft., while 23 range from the coast up to 1,000 ft., 46 to 2,000 ft., 25 to 3,000 ft., 28 to 4,000 ft., 42 to 5,000 ft., and 16 to 6,000 ft. altitude.

State forestry (*Gard. Chron., 3. ser., 26 (1899), No. 675, p. 418*).—A review is given of a paper read by D. E. Hutchins, conservator of forests, Cape Town.

Some timber trees of Queensland, I. W. Fawcett (*Queensland Agr. Jour., 6 (1900), No. 1, pp. 47–49*).—Notes are given on the timber value of *Tristania conferta*, *T. laurina*, and *Backhousia citriodora*. Botanical descriptions, vernacular names, and notes on distribution are also given.

Tree planting in South Australia, A. F. Noll (*Queensland Agr. Jour., 6 (1900), No. 1, pp. 49, 50*).—An extract is given of a paper on this subject in which experiments in tree planting are described. The sugar gum (*Eucalyptus corynocalyx*), is said to be one of the most valuable trees for planting in arid regions.

Useful Australian plants, J. H. Maiden (*Agr. Gaz. New South Wales, 11 (1900), No. 1, pp. 19–22, pls. 2*).—Notes are given on the botanical characteristics, timber quantity, insect enemies, and distribution of the forest red gum (*Eucalyptus tereticornis*) and the yellow box (*E. melliodora*).

The eucalyptus in the Tropics, J. Gifford (*Forester, 6 (1900), No. 1, pp. 11–13, fig. 1*).—A popular account is given of the rapid growth and value as a sanitary agent of eucalyptus trees.

Notes on the sal coppice forests of Oudh, S. Eardley-Wilmot (*Indian Forester, 25 (1899), No. 7, App. pp. 21*).

Notes on improvement fellings in sal forests, S. Eardley-Wilmot (*Indian Forester, 25 (1899), No. 7, App. pp. 17*).

The treatment of some resinous forests in France (*Indian Forester, 25 (1899), No. 11, pp. 1–44*).—Notes on the management of a number of forests in different parts of France.

The decay of forest and shade trees, A. C. Forbes (*Gard. Chron., 3. ser., 26 (1899), No. 669, p. 308*).—Notes the causes of many decays of trees and suggests possible prevention.

The influence of forests upon storage reservoirs, J. D. Schuyler (*Forester, 5 (1899), No. 12, pp. 285–288*).—The author reviews some of the forestry conditions in Europe, and states some of the conditions essential to the maintenance of stream flow and water conservation.

Recent investigations on the effect of lightning on trees, R. Hartig (*Centbl. Gesam. Forstw., 25 (1899), No. 12, pp. 523–544, figs. 29*).

The Haskin process of vulcanizing timber, J. Nisbet (*Indian Forester, 25 (1899), No. 10, App. pp. 1–10, figs. 6*).—Notes are given on antiseptic treatment for the protection of railway and other timber against decay.

Injection of wood (*Sci. Amer., 82 (1900), No. 4, p. 51*).—A method of injection of copper salts in railroad ties for their preservation is described.

The forestry schools of Europe, S. W. Fletcher (*Amer. Gard., 21 (1900), No. 275, pp. 219, 220*).—Notes on the schools of forestry in Germany, Belgium, Denmark, France, Holland, and other European countries.

SEEDS—WEEDS.

Alkali studies—III, B. C. Buffum (*Wyoming Sta. Rpt. 1899, pp. 40*).—This report contains a detailed statement of the experiments described in a previous bulletin (E. S. R., 10, p. 1025). It deals principally with the effect of alkali on the germination of seed.

The author's summary is as follows:

"(1) The presence of very small amounts of sodium sulphate, sodium chlorid, magnesium sulphate, or sodium carbonate undoubtedly has a beneficial effect on the germination of seeds and growth of plants. Large amounts of the same salts retard germination.

"(2) Of the salts most abundant in the alkali of the arid regions those that have the greatest detrimental effects on germination, in order, are sodium carbonate, sodium chlorid, sodium sulphate, and magnesium sulphate.

"(3) The retarding effect of a salt solution on the germination of seeds is in direct proportion to its osmotic pressure, except where other factors enter in, such as the caustic effect of sodium carbonate, or where solutions are very dilute."

Alkali studies—IV, E. E. SLOSSON (*Wyoming Sta. Rpt. 1899, pp. 29*).—A detailed account is given of experiments to determine the rate and amount of water imbibed by seeds from various salt solutions, comparisons being made with the rate at which distilled water is imbibed. The investigations were conducted with wheat, sunflower, peas, buckwheat, rape, and scirpus. In order to show that the rate of imbibition is not affected by the vitality of seed, similar experiments were conducted with seeds that had been killed by vapors of formalin, with old seed, and bits of wood. The author's summary of his results is as follows:

"Experiments on the imbibition of water by a large number of different kinds of seeds show that in all cases the presence of salts in solution hinders the absorption of water. Isosmotic solutions produce nearly the same effect, showing that the osmotic pressure is more important than the kind of salt. Retardation of imbibition does not increase proportionally with the osmotic pressure or with the concentration of the solution, but less rapidly. An osmotic pressure of five or ten atmospheres retards the imbibition of water to a considerable extent with all seeds, and in dilute solutions a difference of one atmosphere makes a perceptible difference in most cases. Salts are absorbed from solution by seeds, but not in the proportion in which they exist in the water. The accumulation of salt in the seed is gradual, so the osmotic pressure of the solution in the seed tends to approach that outside. That the imbibition of water is not due to the action of life is shown by the fact that similar results are obtained from living and dead seeds and dry wood. Dilute solutions of the common alkali salts do not poison the seed or prevent its germination when the conditions become more favorable. Different salts are absorbed from solutions in proportion to their diffusibility. The percentage of water imbibed by seeds in distilled water before their germination is as follows: Corn 106, sunflower 137, peas 120, buckwheat 65, rape 57, scirpus 33, and wheat 62. The germination of seeds in various salt solutions gives results similar to those on the imbibition of water. Wyoming alkali consists principally of sodium sulphate, sodium chlorid, and magnesium sulphate in varying proportions, but in some parts of the State the magnesium sulphate is replaced by sodium carbonate."

The influence of the temperature of liquid hydrogen on the germinative power of seeds, W. THISELTON-DYER (*Proc. Roy. Soc.* [*London*], *65* (*1899*), *No. 420*, *pp. 361–368*).—In connection with Prof. Dewar the author conducted a series of experiments to test the effect of extremely low temperatures on the germination of seeds. Mustard, peas, vegetable marrow, musk, wheat, and barley were subjected to temperatures of —250 to —252° C. for an hour, care being taken that the seed should be cooled gradually to avoid injury by the sudden creation of a vacuum. The seeds were later sown in a cool greenhouse without heat, and in 4 days had germinated. The germinations were: Mustard 100 per cent, peas 100 per cent, vegetable marrow 96 per cent, wheat 96 per cent, barley 100 per cent. Musk, on account of the extreme smallness of the seed, was not counted, but the germination is reported as good. A few days later a mixed lot of seeds of the same kind, with the exception of the musk, was immersed in liquid hydrogen for more than 6 hours. In this case the drop in temperature was sudden, no attempt being made to prevent the formation of a vacuum. No injury was visible which could be traced to the severe cold through which the seeds had passed. They were sorted and immediately sown, with the result that 4 days later every seed had germinated. The author discusses at some length the physiological bearing of this experiment.

On the after ripening of the small grains, A. ATTERBERG (*K. Landt. Akad. Handl. Tidskr., 38 (1899), No. 4, pp. 227–250; Tidskr. Landtmán, 20, pp. 477–482*).—The author investigated the conditions under which imperfectly ripened seed of barley and rye may be brought to full ripeness, and the temperatures most favorable to the germination of such seed. It was found that in order to reach a complete and rapid germination of seed that had not been thoroughly ripened the germination temperature must be lowered from 20° C. (68° F.), now commonly used, to 15° C. (59° F.). All samples examined germinated rapidly and completely at the lower temperature. Rye and barley should germinate completely in 8 days at this temperature; wheat, and probably oats, in 10 days. Seed not germinated in this length of time are either dead or so immature that their value is uncertain.

Many different degrees of ripeness were observed to exist, characterized by different maximum temperature limits for complete germination. Some seeds will germinate completely at 15° C., but incompletely at 19°; others completely at 18, 22, and 27°, and incompletely at 22, 25, or 34°, respectively. The after ripening goes through numerous stages and is not complete until the maximum germination is reached at 30° C. (86° F.). Above this temperature a complete germination was not reached. The safest temperature for increasing the germination of seed grain and least dangerous for its germination was found to be 30 to 40° C.—F. W. WOLL.

The weed seeds of clover and grass seed, with special reference to their place of origin, O. BURCHARD (*Die Unkrautsamen der Klee- und Grassaaten mit besonderer Berücksichtigung ihrer Herkunft. Berlin: Paul Parey, 1900, pp. 100, pls. 5*).—In this book the author discusses the bearing of weed seed on the determination of the origin of commercial seeds, the distribution of various weed seed throughout the regions where clover and grass seed are produced, and studies of weed seed. Short descriptions are given of the weed seed which have been found by him in commercial samples of clover and grass seed, the size, general appearance, color, and external structure of the seed being described with considerable minuteness. In all 378 weed seeds are described. From a tabular arrangement of some of the more common, it appears that 94 species of weed seed characterized the clover and grass seed of middle, eastern, and southern Europe, while 33 are said to be characteristic of North American seed, and 7 of South American seed.

Keys are given for the generic determination of the seeds of Compositæ and Labiatæ found in grass and clover seed.

The weeds of alpine meadows and pastures, F. G. STEBLER (*Landw. Jahrb. Schweiz, 13 (1899), pp. 1–120, pls. 20, figs. 40*).—The author discusses the most important weeds of alpine meadows and pastures, giving data relating to their duration, growth, distribution, and amount of injury done. Suggestions are also given for the destruction of the injurious species, fertilizing, grazing, cutting, burning, pulling, digging out, and plowing the soil being the principal methods suggested.

In the second part of the report descriptions and specific directions for eradication are given for nearly 100 obnoxious meadow plants. These are divided into the woody species, 24 in number, and the herbaceous species, 68 in number.

The present status of the Russian thistle in Washington, C. V. PIPER (*Washington Sta. Bul. 37, pp. 14, map 1*).—This weed was first detected in the State in 1897 and a number of points of infection were located. Contributions were made by the county boards of a number of counties for its eradication, which included a thorough inspection of the railway lines of eastern Washington, and in most cases the destruction of patches of Russian thistles that were found. In 1898 further investigations were conducted and attempts made to eradicate the weed wherever found. With 3 exceptions, all the patches found were along railways.

It was demonstrated that the Russian thistle produces in eastern Washington two crops a year, the first becoming full grown in July and August, at which time the second crop consists of small plants an inch or two high. Where the larger plants were cut in July, it was found that in October the second crop was fully developed and the ground as completely occupied as before. To eradicate such patches, the plants must be cut in July or early August and again in September or October. At no point in the State has the Russian thistle become abundant enough to result in actual loss. It is thought probable that by careful inspection it may be kept in check.

A report of the seed-control stations of Göteborg and Bohus for the year ended June 30, 1899, J. E. ALÉN (*Goteborg, 1900, pp. 14*).—A report is given of the investigations conducted at the seed-control stations in determining the purity, vitality, etc., of a large number of kinds of seed. The results are tabulated and commented upon at some length.

Report of the seed-control station in Hohenheim, O. KIRCHNER (*Wurttemberg. Wchnbl. Landw., 1900, No. 7, pp. 90–95*).—Table showing percentage purity, germination, and worth of 1,442 samples of farm and garden seeds, with comments.

Testing seeds, C. O. TOWNSEND (*Maryland Agr. Col. Quart., 1899, No. 6, pp. 12, figs. 4*).—The author describes the objects and methods of seed testing, gives the conditions essential for germination, describes various kinds of apparatus used in testing, gives directions for selecting samples, table of germination standards, etc. Much of the information is compiled from Yearbooks of this Department.

Germination of seeds, A. H. WARD (*Amer. Gard., 21 (1900), No. 274, p. 209*).—The temperature and moisture conditions involved in the germination of a number of farm and garden seeds are discussed, and tables given showing the minimum, maximum, and optimum temperatures for the germination of wheat, barley, peas, corn, beans, and squashes, and for the water absorption of the air-dried seeds of mustard, millet, corn, wheat, buckwheat, barley, turnips, rye, oats, hemp, beans, peas, clover, beets, and white clover. Soaking seeds in pure water tends to dissolve out materials needed in the germination and growth of seeds. The author recommends soaking in a solution of some fertilizer salt which will add to, rather than detract from, the vigor of the seeds.

The increase in mineral matter during germination, G. André (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 26, pp. 1262-1265*).—A large number of experiments with *Phaseolus multiflorus* are reported, in which plants were analyzed at short intervals from germination. They were found to lose in dry weight for a considerable period, while the total weight of the ash increased. In no case was the experiment conducted long enough to have the plant establish itself or exercise the chlorophyll functions for any length of time.

On the hygrometric condition of seeds, L. Maquenne (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No 20, pp. 773-775*).—Notes are given on the action of seeds in which there is an attempt to equalize the amount of water contained by the seed and that existing in the surrounding air. In this respect the seeds act as inert bodies, but it is probable that this relation has some bearing upon the latent life of the seed, a topic which the author proposes to discuss at some future time.

Germination of carob seed and production of mannose by a soluble ferment, E. Bourquelot and H. Hérissey (*Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 16, pp. 614-616*).—The authors describe the germination of the carob and claim that during the germination mannose and galactose are formed in the embryo by the action of soluble ferments existing in the seed.

Composition of endosperm of carob seed, E. Bourquelot and H. Hérissey (*Compt. Rend. Acad. Sci. Paris. 129 (1899), No. 7, pp. 391-393*).—The carbohydrates, which represent four-fifths of the endosperm of the seed, are said to be chiefly anhydrids of mannose and galactose.

The influence of moisture on germination, W. Kinzel (*Landw. Vers. Stat., 51 (1899), No. 4-5, pp. 351-356*).

The chemical and physiological effect of anæsthetics on the germination of seeds, M. Soave (*Staz. Sper. Agr. Ital., 32 (1899), No. 6, pp. 553-592*).—The effect of chloroform and sulphuric ether upon the germination and chemical composition of the seeds of the peanut, squash, rice, maize, peas, and beans is given.

The action of anæsthetics on the vitality of dry and moist seeds, H. Coupin *Compt. Rend. Acad. Sci. Paris, 129 (1899), No. 15, pp. 561, 562*).—Experiments with wheat and crimson-clover seed, in which dry and moist seeds were subjected to the action of chloroform and carbon bisulphid. The experiments were repeated with dry and moist seed of the white lupine, crimson clover, hairy vetch, buckwheat, wheat, barley, maize, and hemp, from which it appeared that the vitality of moist seeds is seriously affected by anæsthetics.

On the analysis of sugar-beet seed, A. Vivien and Sellier (*Bul. Assoc. Chim. Sucr. et Distill., 17 (1899), Nos. 2, pp. 117-133, figs. 5; 3, pp. 197-216, fig. 1; 4, pp. 281-307, fig. 1*).

The testing of sugar-beet seed, A. M. Julhiard (*Bul. Assoc. Chim. Sucr. et Distill., 17 (1899), No. 2, pp. 134-145*).

On the occurrence of histidin and lysin in germinating seeds, E. Schulze (*Ztschr. Physiol. Chem., 28 (1899), No. 5-6, pp. 465-470*).—These substances are said to be products of proteid metabolism in germinating seed.

Histidin and lysin as metabolic products in conifer seeds, E. Schulze and E. Winterstein (*Ztschr. Physiol. Chem., 28 (1899), No. 5-6, pp. 459-464*).

Color variation in seed of Trifolium, A. Preyer (*Inaug. Diss., Berlin, 1899; abs. in Bot. Centbl., 81 (1900), No 7, pp. 243-245.*)

Weeds, J. FIELDS (*Oklahoma Sta. Rpt. 1899, pp. 77, 78*).—Brief notes are given on methods for eradicating weeds, the recommendations given being those suggested in Bulletin 41 of the station (E. S. R., 11, p. 354).

The occurrence of a new species of cuscuta on alfalfa, E. SCHRIBAUX (*Jour. Soc. Agr. Brabant-Hainaut, 1899, pp. 716–718*).

Poisonous weeds in the Springsure District, J. F. BAILEY (*Queensland Agr. Jour., 6 (1900), No. 1, pp. 39–42, pls. 3*).—The following plants are either known or suspected of being poisonous to stock: *Macrozamia moorei, Asclepias curassavica, Datura leichhardtii, Carissa ovata, Lactuca scariola, Cassia sophera, Swainsonia galegifolia, Eremophila maculata, Myoporum acuminatum*, and *M. deserti.*

Chemistry and the struggle with noxious herbs, J. GRAFTIAU (*L'Ing. Agr. Gembloux, 10 (1900), No. 6, pp. 413–428*).

DISEASES OF PLANTS.

A report on plant diseases studied during the year 1898 at the experiment station for plant protection at Halle, M. HOLLRUNG (*Jahresber. Vers. Stat. Pflanzenschutz, Halle, 10 (1898), pp. 35–64, figs. 3*).—A report is made on insect, fungus, and nematode diseases of cereals, sugar beets, potatoes, garden vegetables, and fruit and shade trees.

Among the enemies of cereals the author mentions *Dorcadion lineatum, Anisoplia agricola, Bibio hortulanus, Tipula pratensis, Cephus pygmæus, Ophiobolus herpotrichus*, and *Erysiphe graminis.*

White grubs, nematode worms, plant lice, and species of Silpha are considered the most important enemies of the sugar beet. *Rhizoctoma violaceæ* is an important fungus disease of this crop.

Among potato diseases, the author gives notes on the potato rot, scab, and attacks of the larvæ of *Eumerus lunulatus.*

Among fruit insects, attention is given to *Anthonomus pomorum, Rhynchites betuleti, Gastropacha quercifolia, Lyonetia clerckella*, oyster-shell bark-louse, and woolly aphis. Brief notes are given on *Fusicladium dendriticum* and *Peronospora viticola.*

The station received a number of proprietary substances for experimental purposes during the year. Antiherbium was tried for destroying weeds. One kilogram of this substance was dissolved in 28 liters of water and sprayed upon 10 square meters of land, upon which the following weeds were growing along with the grass: Leontodon, *Lamium album*, Plantago, and *Polygonum convolvulus.* The leaves of the Plantago and Polygonum were slightly burned; otherwise the substance seemed to be ineffective. Verminol was tried in the destruction of insects. The substance proved to be unsatisfactory. In experiments with calcium carbid in combating phylloxera, this substance gave unsatisfactory results.

Investigations on the prevention of wheat smut in Bavaria during 1898, DOBENECK (*Vrtljschr. Bayer. Landw. Rathes, 4 (1899), No. 3, pp. 255–282*).—An account is given of investigations on wheat smut in Bavaria. A compilation is made from a large number of reports on the occurrence of smut in different regions and as to the susceptibility of different varieties to disease. The beneficial results of soaking seed in copper-sulphate solutions, after which the seed are placed in lime solutions, and the Jensen hot-water treatment are mentioned, although from the data given no experiments seem to have been made with the hot water. The value of clean seed is commented upon, and threshing machines are given as a means by which the disease is widely spread.

Leaf scorch of the sugar beet, cherry, cauliflower, and maple, F. C. STEWART (*New York State Sta. Bul. 162, pp. 165–178 pls. 6*).—In August, 1899, the attention of the author was called to fields of sugar beets which were reported to be blighting. The so-called blight was characterized by the dead-leaf margins of slightly affected plants. In more severe cases the young leaves at the center of the crown were black and dead, as were the blades of the leaves. In the majority of cases the roots appeared normal, but the plants most severely attacked often showed a brown discoloration. The discolored tissue showed no indication of rot, but was separated from the healthy tissue by an indefinite, somewhat irregular line. The discoloration of the root is a physiological effect due to the death of the foliage rather than any parasitic organism.

The only other disease with which the leaf scorch is likely to be confused is the leaf spot, although in advanced stages it might be mistaken for the scab. In general it may be distinguished from the scab by the light-brown discoloration of the sound tissue. Affected roots were analyzed for sugar content, and showed that it was very appreciably reduced. Concerning treatment, it is stated that proper irrigation would prove a sure preventive of this disease, but where irrigation can not be practiced, the farmer should avoid planting on a light sandy soil, and in dry weather should conserve the moisture by stirring the soil frequently and especially after every shower.

In September of 1899 attention was called to a scorching of cherry foliage, which it was feared might prove an infectious disease like the fire blight of the pear and apple. On trees of all ages more or less of the foliage was brown, crisp, and dead. An examination made in the orchard showed that of 715 trees but 2 were unaffected, and six-sevenths of all the trees showed 75 per cent or more of the foliage scorched. The principal variety in this orchard was Montmorency, and it seems more commonly affected than any, although the English Morello and some others have shown it to a considerable extent. From the experience of the owners of the orchard, it is thought that little harm will result from the scorching of the foliage, on account of its appearance late in the season, although the subject is to be investigated further.

In September the entomologist of the station reported cauliflower leaves with their margins blackened and shriveled, accompanied with the statement that the partly unfolded leaves of cauliflower on eastern Long Island were generally affected in this manner. The author visited the region and found the affected leaves were growing and appeared normal except their crisp brown or black margins. Large plants were more severely injured than small ones, and the worst affected field observed was one in which the plants were large and thrifty and had begun to form heads. As with the beet and cherry scald, the exact time of injury was unknown, but it probably occurred during the last days of August. During this time there was continuous fog, but without rain, and it is the author's opinion that the injury was due to the hot sun falling upon the young leaves, which were unusually tender on account of having grown in foggy weather. The amount of damage done by tip burn to cauliflower was small.

A brief account is given of leaf scorch of Norway and sugar maples, due to physiological causes, as above. It happens whenever the quantity of water transpired by the leaves is greater than that which the roots can supply, and this condition may be brought about in several ways. Ordinarily, no serious injury is done by the disease, although in recently transplanted trees the effects may prove disastrous.

Apple scab in the Potlatch, L. F. HENDERSON (*Idaho Sta. Bul. 20, pp. 79-96, pls. 3*).—In 1897 this disease was located in what is known as the Potlatch district in Idaho, one of the principal fruit regions of this State. It is briefly described together with remedial treatment, such as spraying with copper sulphate solution, Bordeaux mixture, and ammoniacal copper carbonate.

In 1899 experiments were conducted by the station officers in an orchard that was badly infested with the disease. Two sprayings of Bordeaux mixture, or one spraying of copper sulphate and one of Bordeaux mixture, were given the trees, and in addition to a great reduction in the amount of apple scab present, it was also found that not more than half as many wormy apples were found upon the sprayed trees as upon those which had not been sprayed. The cost of the 2 applications per tree was 10 cts.

Spraying, L. R. TAFT (*Michigan Sta. Rpt. 1898, pp. 129-131*).—An account is given of a series of experiments conducted on peach trees to prevent leaf curl. The materials tested were a solution of copper sulphate at the rate of 1 lb. in 15 gal. of water, Bordeaux mixture containing 4 lbs. of copper sulphate and 10 lbs. of lime to 40 gal. of water, and a whitewash with the same amount of lime as in the Bordeaux mixture. These materials were applied to 10 trees each in March, and frequent examination during the growing season showed that there was but little difference in the efficiency of the 3 preparations, but a marked difference when the sprayed trees were compared with the unsprayed trees.

In order to learn if spraying would be beneficial after the leaves had developed, part of the unsprayed trees were treated with the 3 preparations mentioned above. The conditions were very unfavorable for the spraying, but from the experiments as well as results obtained in previous years, it seems that the application of fungicides to peach trees any time after the leaves have fallen and before the first of April will prevent the attack of leaf curl. Where spraying was neglected until the buds had begun to open and the fruit had set, the results were not satisfactory, although little difference was noticed in the results secured from the different fungicides. Copper sulphate solution, on account of its easy preparation and application, is recommended for the earlier applications.

The prevention of leaf disease in coffee, J. CAMERON (*Rpt. Supt. Govt. Gardens, Mysore, 1899, pp. 23*).—After reviewing the physical conditions of the country, the usual practice of cultivation of coffee is described. The value of different manures and methods of application is stated, and some results obtained by crossing and hybridizing are described.

Among the coffee pests, the most destructive is *Hemileia vastatrix*. This fungus partially or wholly destroys the leaves and persistently follows the coffee wherever cultivated. A virulent attack on an experimental plat in the gardens was temporarily checked by burning every infected leaf and coating the ground with a thick layer of lime. Spraying with a copper sulphate solution has also held the disease in check.

A leaf rot due to *Pellicularia koleroga* is described which frequently causes serious injury. The burning of infected leaves, application of flowers of sulphur in the early stages, or Bordeaux mixture and similar fungicides are recommended.

The principal insect pest of the coffee is *Xylotrechus quadrupes*. The method of attack of this insect is described, and remedies suggested.

The author emphasizes the necessity for better cultivation and proper fertilization of the crop. In this way the plants are made more healthy and are able to withstand insect and fungus attacks to a greater degree. Hybridization of varieties is thought to offer promising results, and next to this the interchange and special selection of seed is recommended.

The most efficient form of combination of copper fungicide and soap mixtures, M. HOLLRUNG (*Landw. Jahrb., 28 (1899), No. 3-4, pp. 593-616*).—The author has investigated the effect of adding soap to a number of the more common fungicides, such as Bordeaux mixture, copper sulphate solution, ammoniacal copper carbonate, copper-soda mixture, Burgundy mixture, and copper carbonate solution. The effect of different kinds of soap on the mechanical condition of the fungicide is shown by the amount of precipitate formed when the mixture is allowed to stand for a short time.

Formulas are given for making Bordeaux mixture, copper carbonate mixture, copper sulphate and ammonia, and ammonium copper carbonate solution with hard, soft, resin, and petroleum soaps. The characteristics of such mixtures are described and their uses given.

The cereal rust problem, G. MASSEE (*Nat. Sci., 15 (1899), No. 93, pp. 337-346*).—Discusses Eriksson's mycoplasma theory.

Rust in wheat—a probable preventive, W. DEACON (*Queensland Agr. Jour., 5 (1899), No. 2, pp. 162–164*).

A supposed new potato disease (*Agr. Gas. [London], 50 (1899), No. 1339, p. 162*).

The ring scab of sugar beets, FRANK (*Bl. Zuckerrübenbau, 6 (1899), No. 23, pp. 353–356, fig. 1*).—This article has been previously noted (E. S. R., 11, p. 861).

White rot of turnip, M. C. POTTER (*Extr. Proc. Durham Phil. Soc., 1899, Nov., pp. 3*).—A bacterial disease is briefly described.

Injury by sun scorching of foliage, F. H. HALL and F. C. STEWART (*New York State Sta. Bul. 162, popular ed., pp. 6, pl. 1, figs. 2*).—A popular edition of Bulletin 162 (see p. 1058).

A new disease of the short-leaved pine, A. P. ANDERSON (*South Carolina Sta. Rpt. 1898, pp. 16, 17*).—A note stating that investigations have been begun on a new disease of the short-leaved pine which is similar to the European larch "canker," and which is very common in the upper part of the State.

Leaf cast of pines and its prevention, CIESLAR (*Centbl. Gesam. Forstw., 25 (1899), No. 11, pp. 506–509, figs. 2*).—Notes on *Hysterium pinastri* and methods for its control. Spraying with copper fungicides is recommended.

A leaf browning of larch, R. HARTIG (*Centbl. Gesam. Forstw., 25 (1899), No. 10, pp. 423–426, fig. 1*).—*Allescheria laricis*, n. sp., is described. It attacks the leaves of larch, causing them to turn brown and later fall from the tree.

A new parasite of Carpinus betulus, R. HARTIG (*Centbl. Gesam. Forstw., 25 (1899), No. 11, pp. 485, 486, fig. 1*).—Notes are given on a disease of this tree, the cause of which is said to be the fungus *Phoma sordida*.

A sclerotid disease of beech roots, H. VON SCHRENK (*Rpt. Missouri Bot. Gardens, 10 (1899), pp. 61–70, pls. 2; abs. in Bot. Centbl., 80 (1899), No. 7, p. 278*).—A disease of beech roots is described, the mycelium of which is probably one of the Hymenomycetes.

A disease of osiers, V. DUCOMET (*Jour. Agr. Prat., 1899, II, No. 44, pp. 625–627, figs. 4*).—A disease of willows is described in which the leaves are attacked by *Glœosporium salicis*. Collecting and burning the fallen leaves is recommended, and where the attack is especially severe recourse should be made to some of the well-known fungicides.

Nitrogen hunger and coffee disease, H. B. EVANS (*Planting Opinion, 4 (1899), No. 51, pp. 1009–1012*).

Cacao disease in Trinidad (*Kew Misc. Bul., 1899, No. 145–146. pp. 1–6, pl. 1*).—This disease, due to *Phytophthora omnivora*, with which is associated *Nectria bainii*, has been noted from another source (E. S. R., 11, p. 362).

On the occurrence of bacteria in abnormal enlargements on roots of Phaseolus multiflorus, O. SCHWAN (*Inaug. Diss., Erlangen, 1898, pp. 36; abs. in Centbl. Bakt. u. Par., 2 Abt., 5 (1899), No. 24, pp. 847, 848*).—An account is given of an abnormal swelling of the roots of *Phaseolus multiflorus* which was caused by bacteria. The organism was separated, cultivated in various media, and its characteristics described.

The parasitism of Phoma reniformis and its rôle in black rot of grapes, N. V. SPESCHNEW (*Ztschr. Pflanzenkrank., 9 (1899), No. 5, pp. 257–260*).—The author states that the black rot of grapes is due both to *Phoma uvicola* and *P. reniformis*, and that both *P. reniformis* and *P. flaccida* are true parasites.

A parasitic disease of Gloxinia, A. OSTERWALDER (*Ztschr. Pflanzenkrank., 9 (1899), No. 5, p. 262*).—A brief note is given on a disease of gloxinias due to Anguillula.

Bordeaux mixture, J. FIELDS (*Oklahoma Sta. Rpt. 1899, pp. 80, 81*).—Brief notes are given for the preparation and application of Bordeaux mixture.

The action of some copper fungicides on potatoes, M. HOLLRUNG (*Jahresber. Vers. Stat. Pflanzenschutz, Halle, 10 (1898), pp. 7–9*).—Experiments are reported with various forms of Bordeaux mixture in which sugar, soap, petroleum, and Schweinfurt green were added to increase the adhesive power or to add in effectiveness as insecticides.

New fungicides for potato diseases, J. F. Favard (*Rev. Hort., 71 (1899), No. [illegible], pp. 451, 452*).—Copper sulphate 2.5 kg., sodium silicate 1.5 liters, sodium carbonate 800 gm., and water 100 liters is said to form a fungicide of great tenacity and efficiency. It is recommended for use on other plants than potatoes, especially on grapes and orchard trees.

ENTOMOLOGY.

Report of the apiarist, J. M. Rankin (*Michigan Sta. Rpt. 1898, pp. 139-142*).—Twenty-five swarms of bees were wintered in a cellar at a temperature which varied from 44 to 48° F. The swarms passed the winter in good condition. A colony which was supposed to be inoculated with bee paralysis did not develop the disease, and the author regards it as impossible to produce the disease in Lansing.

An experiment was conducted with 4 different kinds of foundation, 30 sections being filled with each kind of foundation. These foundations were Root's XXX, Root's Extra Thin Surplus, Dadant's Extra Thin Surplus, and "No Wall." The results indicate that the Root's Extra Thin Surplus foundation was filled better than the other varieties, and contained a smaller percentage of wax. Dadant's Extra Thin Surplus foundation stood next in these respects. A larger percentage of wax was contained in combs built from lighter foundations than in that from heavier ones.

Experiments were conducted to determine the relative advantages or disadvantages of the plain section. Several supers were fitted with plain sections on one side and open top on the other. In every case the bees worked on the plain sections first and they weighed most at the end of the experiment. In seasons when the honey flow is greater the open-top sections would doubtless outweigh the plain sections, but the latter are more easily cleaned and look better on the market.

Four colonies of bees were transferred on August 1 to the midst of a marsh in which wild bergamot, willow-leafed spirea, coreopsis, goldenrod, and boneset were found in abundance. The colonies were returned to the yard on October 7. The average gain of the 4 colonies which were left at home during this time was 8¾ lbs. each, and the average gain of the 4 colonies taken to the marsh was 39 lbs. each.

Work is being continued upon the problem of lengthening bees' tongues. One direct cross was made with the result that a gain of 0.9 mm. in length was obtained.

Notes on insect pests from the entomological section, Indian Museum, E. Barlow (*Indian Mus. Notes, 4 (1899), No. 4, pp. 180–221, pls. 2, figs. 2*).—In this article the following tea pests receive consideration: *Euproctis latifascia*, *Thosea cervina*, *T. divergens*, *Belippa lohor*, *Astycus lateralis*, *Diapromorpha melanopus*, *Cremastogaster rogenhoferi*, and several beetles, Lepidoptera, and scale insects.

Among insects injurious to cereals and field crops, the author mentions *Tanymecus indicus* injurious to wheat, *Leucania unipuncta* attacking jowari, *Oxycarenus lugubris* on cotton, *Agrotis segetis* and *A. biconica* on indigo, *Plutella maculata* on cauliflower, *Rhopalosephum dianthi* on brinjal, *Acridium peregrinum* attacking a variety of plants, and a number of unidentified insects injurious to the potato and sugar cane.

Among fruit-tree pests, the author gives brief notes on Longicorn beetle injurious to the apple tree, the mango caterpillar, and Psychid caterpillar attacking grapevines.

Economic and biological notes are given on a number of forest insects, among which the following may be mentioned: *Eriococcus paradoxus* var. *indica*, *Diaspis calyptroides* var. *cacti*, *Hyblæa puera*, and a species of Chrysobothris.

The author gives a list of ladybirds, and dipterous and hymenopterous parasites which serve to hold in check the depredations of injurious insects in India. R. P. Lambert reports an experiment in driving away locusts by means of firearms and blank cartridges. Complete success was obtained by this method. D. Hooper advises the use of lye of wood ashes in making arsenical insecticides to be used against locusts.

Pieris brassicæ, W. W. Schipper (*Tijdschr. Plantenziekten, 5 (1899), No. 1, pp. 1–11, pls. 3, figs. 3*).—This insect occurred in unusual numbers in the summer of 1898 and was especially injurious to kale. The author observed that the species was more abundant in gardens and small areas which were near houses and other buildings than in the open field.

Notes are given on the habits and life history of the insect. A large proportion of the cocoons were infested with *Microgaster glomeratus*. There are ordinarily 2 generations a year. The first generation requires for its development about 3 months, from May to July. The second generation develops during the period from August to the following April. The winter of 1897–98 was mild and therefore especially favorable to the development of the winter generation.

In discussing remedies to be used against this insect, the author makes the following recommendations: Kale should be planted in open fields as far as possible from houses, barns, walls, trees, etc. Trap crops may be planted near walls and houses, and later destroyed. The author observed that the deposition of eggs and the process of pupation usually took place upon the bark of trees and near houses and garden walls, and that the moths of the second generation came from the open field to such sheltered places for the purpose of depositing their eggs. It is also recommended that cocoons infested with *Microgaster glomeratus* should be spared as far as possible in order that the parasites may develop, and that wild cruciferous plants should not be allowed to grow in or near fields where kale is to be planted.

A study of diseased larvæ of the gypsy moth, A. Bergman (*Ent. Tidskr., 20 (1899), No. 4, pp. 284–286*).—Diseased larvæ of this moth were received from Prof. Lampa. Upon opening one larva which was already dead, a grayish-brown semifluid mass with a rancid odor was found. Cover-glass preparations showed bacteria in large numbers, being for the most part of 2 sorts. The smaller variety, which was from 1.2 to 2.4 microns in length and 0.6 of a micron in breadth, occurred in much larger numbers than the other variety. The same organisms were found in another diseased larva, which was still alive.

The smaller bacteria grew readily upon gelatin agar and glycerin agar, producing gas with a small content of sulphur. The author tried some inoculation experiments with this organism upon *Lymantria monacha* and *Pieris brassicæ.* The larvæ of the former died 2 days after inoculation, while those of the latter were not affected. Hypodermic injections of pure cultures of the organism in white mice produced no pathogenic results.

Insects and diseases affecting the prune, R. W. DOANE (*Washington Sta. Bul. 38, pp. 37–44*).—The author presents brief notes upon the following insects: San José scale, red spider, plum tree aphis, plum curculio and plum gouger. As a remedy for the San José scale, it is stated that experiments in Washington indicate that the lime, sulphur, and salt wash is the most effective spray. Experiments on the treatment of plants for the red spider indicate that the lime, sulphur, and salt wash, or water at a temperature of 150° F., will kill the eggs of the red spider. These experiments were conducted in the laboratory and have not been confirmed by field tests. The plum-tree aphis is said not to be especially destructive to orchards in the eastern part of the State, although it is rather harmful in the western portion. Kerosene emulsion and quassia chips and whale-oil soap solution are recommended as the most useful insecticides against this insect. Brief reference is made to the flat-headed apple-tree borer and peach-tree borer as injuring the plum tree. The plum curculio and plum gouger have not yet been found in Washington.

Report of the entomologist and assistant horticulturist, E. WALKER (*South Carolina Sta. Rpt. 1898, pp. 19–22*).—This is a summary of the entomological work of the station. The making of a collection of the insects of the State is described and attention is called to the need by fruit growers of combative measures against certain kinds.

Observations on the honey-bearing plants of the maritime Alps, P. J. BALDENSPERGER (*L'Apiculteur, 44 (1900), No. 2, pp. 68–72*).—Notes on the chief honey-bearing plants of this region for each month of the year.

Some insect experiences of 1899, M. V. SLINGERLAND (*Proc. West. New York Hort. Soc. 1900, pp. 49–52*).—Brief notes on the codling moth, tent caterpillars, and on arsenical and other spray materials.

Migration and dispersal of insects, J. W. TUTT (*Ent. Rec. and Jour. Variation, 12 (1900), No. 1, pp. 13–16*).—Observations on a number of species of Lepidoptera.

The alfalfa worm (*University News Letter, Lincoln, Nebr., 1900, No. 6, fol.*).—Notes on the extent of injury caused by this insect, with an account of remedies which have been successfully used against it.

Grass insects, H. OSBORNE (*Agr. Student, 6 (1899), No. 3, pp. 57–59*).—As general preventive measures against the numerous insects which are injurious to grass lands, the author recommends the rotation of crops, the use of trap lights, arsenical baits, and the protection of the natural enemies of injurious insects.

Fruit flies, T. W. KIRK (*New Zealand Dept. Agr. Leaflets for Gard. and Fruit Grow-

ri, No. 35, pp. 5, figs. 2).—The author gives notes on *Tephrites tryoni* and *Halterophora capitata*. The latter species is said to be established in Queensland, West Australia, New South Wales, Tasmania, and South Africa. A brief account is given of its life history and of suitable remedies for use in combating it.

Two pineapple pests, C. P. LOUNSBURY (*Agr. Jour. Cape Good Hope, 16 (1900), No. 2, pp. 94–102, figs. 2*).—*Dactylopius longispinus* was probably introduced on infested pineapples from Natal. Thorough inspection of imported pineapple sprouts is recommended. As remedial measures, the author suggests the use of a resin wash and digging up and burning badly infested plants. Fumigation with hydrocyanic-acid gas is not recommended.

Brief notes are given on *D. bromeliæ* and *D. brevipes*. The author presents a brief account of *Aulacaspis bromeliæ*. This scale insect is not yet widely distributed in the pineapple districts of Cape Colony but has been observed on pineapples in greenhouses. The species is well established in Natal. Fumigation with hydrocyanic-acid gas is recommended. One hymenopterous parasite has been bred from this scale.

Enemies and diseases of coffee, H. LECOMTE (*Le café. Paris: G. Carré & C. Naud, 1899, pp. 176–206, figs. 7*).—This article constitutes chapter 12 of the author's book on "Coffee" and contains notes on the various nematode, insect, and fungus diseases of the coffee plant. Among the more important insect enemies, the following may be mentioned: *Xylotrechus quadrupes, Cucujus coffeophagus, Zeuzera coffeæ, Elachista coffeella, Cemiostoma coffeella*, and a number of species of bark lice. *Aræocerus fasciculatus* is mentioned as an enemy of the coffee berry. A list of parasitic fungi which are found upon coffee is given, and notes are presented on some of the more important fungus diseases, among which may be mentioned *Hemileia vastatrix* and *Pellicularia koleroga*.

Insects infesting carnations, F. A. SIRRINE (*Amer. Florist, 15 (1900), No. 613, pp. 909–913, figs. 6*).—Notes on the life history and remedies for *Rhopalosiphum dianthi*, red spider, tobacco thrips, *Peridroma saucia, Plusia brassicæ*, white ants, and *Cacœcia rosaceana*.

A mole cricket (*Jour. Dept. Agr. West. Australia, 1899, Dec., p. 23*).—Recommends poisoned cabbage leaves and the use of carbon bisulphid and kerosene in the ground in the control of this insect.

New contribution to the knowledge of Italian insect galls. Fourth communication, C. MASSALONGO (*Nuovo. Gior. Bot. Ital., n. ser., 6 (1899), No. 2, pp. 137–148*).

Some muscinæ of North America, G. DE N. HOUGH (*Biol. Bul. 1 (1899), No. 1, pp. 19–33, figs. 20*).—Notes on the classification and biology of species belonging to the following genera: Stomoxys, Hæmatobia, Hemichlora, Muscina, Clinopera, Pyrellia, Mesembrina, Graphomyia, and Morellia.

A first list of Acaria collected in Portici, G. LEONARDI (*Ann. Regia Scuola Superiore Agr. Portici, 2. ser., 1 (1899), pp. 493–525*).—A list of mites, together with notes on their hosts and life habits.

The life history of Brachysoma codeti, P. CHRÉTIEN (*Ann. Soc. Ent. France, 68 (1899), No. 3, pp. 451–465, pl. 1*).—The author gives detailed descriptions of the insect in all its stages, together with notes on its relationship to allied species.

The wheat midge (Cecidomyia tritici), S. L. MOSLEY (*Nat. Jour., 9 (1900), No. 91, pp. 13, 14, figs. 5*).—Brief popular notes on this insect.

Notes on the life habits and injurious action of Cetonia, J. RITZEMA-BOS (*Tijdschr. Plantenziekten, 5 (1899), No. 1, pp. 12–23*).—An elaborate discussion of the literature concerning the life habits, especially of the larval condition, of *Cetonia floricola* and other species, and on their host plants.

Craniophora (Acronycta) ligustri var. olivacea, D. T. HAAR (*Tijdschr. Ent., 42 (1899), No. 3. pp. 97–100, fig. 1*).—This insect feeds on the ash. A second brood was produced in an insectary, but these individuals would probably perish if left to themselves during cold autumn weather.

The parasites of Lymantria monacha, C. AURIVILLIUS (*Ent. Tidskr., 20 (1899),* *No. 4, pp. 279–281*).—Records as parasites of this insect *Ichneumon nigritorius, Pimpla instigator, P. examinator, P. arctica, P. brassicariæ, P. quadridentata, P. didyma, Theronia flavicans*, and *Tachina fasciata*.

Life history of "tun twig borer" (Magiria robusta), B. O. Coventry (*Indian Forester, 25 (1899), No. 9, pp. 267–370*).—The larvæ of this insect enter the tun twigs in the axil of the leaves. There are two generations a year. In fighting this insect the author recommends cutting back the shoots which have been attacked about the middle of September.

The elm twig-girdler (Oncideres cingulatus), P. J. Parrott (*Trans. Kansas Acad. Sci., 6 (1899), pp. 200–202, figs. 4*).—Notes on the habits and life history of this beetle.

Physopoda as enemies of sugar peas, F. Trybom (*Ent. Tidskr., 20 (1899), No. 4, pp. 267–277*).—*Pisum sativum* was attacked by a number of species of this order of insects. The author presents descriptive and economic notes on *Thrips physopus, T. communis, Physopus atrata* and *P. robusta*.

Thrips communis was observed feeding upon *Vicia villosa, Onobrychis sativa, Medicago sativa*, and *Lupinus luteus*. *Physopus robusta* attacked *Pisum arvense* as well as *P. sativum*. The author gives a detailed description of the larvæ of *P. robusta*.

Pulvinaria camellicola and means of combating it, G. Leonardi (*Ann. Regia Scuola Superiore Agr. Portici, 2. ser., 1 (1899), pp. 389–403, figs. 11*).—The author gives detailed descriptions of the larval, nymphal, and adult forms of both sexes of this insect. The larvæ appear during the latter part of April and the first part of May. For a period of 3 or 4 days they wander about the host plant with considerable activity in search of a place for fixing themselves. The larvæ attach themselves preferably to the under surface of the leaves, along the midrib and other veins. The adults of the first generation appear during the first week of August and deposit the eggs which develop into the second generation during the latter part of August and the first part of September. The host plants which are preferred by this insect are *Camellia japonica, Euonymus japonica*, and *Podacarpus elongata*.

The San José scale, J. Ritzema-Bos (*Tijdschr. Plantenziekten, 5 (1899), Nos. 2, pp. 33–96; 3–4, pp. 97–127; 5–6, pp. 145–167, figs. 31, map 1*).—This article contains an extended and critical discussion of the literature relating to the San José scale and allied species, including the following subjects: The life habits, methods of reproduction, food plants, injurious action, methods of distribution, conditions upon which the distribution of the insect depends, the various methods which have been adopted for combating the insect, and notes on the habits and life history of *Lecanium persicæ, Mytilaspis pomorum, Aspidiotus camelliæ, A. ostreæformis, Diaspis fallax*, and other related species. A bibliography of American and other work on the San José scale is appended to the article.

The San José scale question from a horticultural standpoint, S. A. Beach (*Proc. West. New York Hort. Soc. 1900, pp. 19–24*).

The enemies of the migratory locusts (Schistocerca paranensis), C. Berg (*Comunic. Mus. Nac. Buenos Aires, 1 (1898), No. 2, pp. 25–30*).—Notes on *Mermis acridiorum, Agria acridiorum*, and *Trox suberosus*.

Depredations of Tipula in meadows, Ewert (*Ztschr. Pflanzenkrank., 9 (1899), No. 6, pp. 328, 329*).—The author makes a report upon an unusually severe attack of the larvæ of crane flies upon the roots of grasses. The larvæ belong to 2 species, *Tipula oleracea* and *T. nigra*. They were found at a depth of from 1 to 2 cm. beneath the surface and were so abundant that from 10 to 20 could be found in a square foot of surface. The grasses were completely killed in the infested areas, as well as all other forms of vegetation, with the exception of reeds and *Plantago maritima*.

Borers in trees, J Fields (*Oklahoma Sta. Rpt. 1899, p. 80*).—Painting the trunks of trees with a mixture of soft soap and a strong solution of washing soda has been used with success in preventing the laying of eggs on the bark.

Killing insects in stored grain, J. Fields (*Oklahoma Sta. Rpt. 1899, p. 81*).—Brief directions are given for the use of carbon bisulphid in killing insects in stored grain.

Destruction of insects, E. E. Bogue (*Oklahoma Sta. Rpt. 1899, pp. 37, 38*).—The author insists upon the timely application of insecticides and calls attention to the value of domestic fowls and the horned toad as insect destroyers.

FOODS—ANIMAL PRODUCTION.

Nitrogen equilibrium in adult man, V. O. Sivén (*Skand. Arch. Physiol., 10 (1899), No. 1–2, pp. 91–148, pl. 1*).—A number of experiments with man are recorded in which the balance of income and outgo of nitrogen was determined. Some of the principal deductions follow:

The experiments show that the adult human organism can remain in nitrogen equilibrium at least for a short time without increasing the fuel value of the diet when the food furnishes only 4.52 gm. of nitrogen (equal to 28.3 gm. of protein per day), and only about 0.2 gm. of the nitrogen is in the form of true albumen. Calculated per kilogram of body weight, 0.08 gm. of nitrogen, of which 0.03 gm. is nitrogen of true albumen, represents the minimum requirement.

When the organism is in nitrogen equilibrium at the lowest limit and the fuel value of the diet is not less than normal, the organism does not lose any of its own protein, either "circulating" or "organic." Further, the amount of protein in the diet is not dependent upon the protein content of the body tissue. The author believes his experiments warrant the deduction that the nonproteid nitrogen compounds in the diet are not as directly excreted from the organism as has been believed. As regards the source of muscular energy, in the author's opinion, all the experiments indicate that muscular contraction takes place at the expense of nitrogen-free nutrients.

Experimental investigations on the effects of muscular work on metabolism and the value of the several nutrients as sources of muscular energy, H. N. Heineman (*Inaug. Diss., Munich, 1898, pp. 51*).—A number of experiments on the value of the different nutrients as sources of muscular energy and the effects of muscular work on metabolism were made with a healthy man. The test covered a number of periods, in which the diet consisted chiefly of protein, of fat, or of carbohydrates. The amount of work performed was measured with a Gaertner ergostadt. The respiratory quotient was measured by means of a Magnus-Levy appaıatus. In a number of the experiments the nitrogen and fuel value of urine were determined, these factors being compared with similar factors in the diet.

The author's principal conclusions were that Chauveau's belief that when fat is burned in the body more energy is required than in case of carbohydrates is incorrect. He regards it as much more probable that the different nutrients are available for muscular work very nearly in proportion to their heats of combustion. In the experiments reported the respiratory quotient for work and rest was the same. Under ordinary conditions the author considers fat and carbohydrates the source of muscular energy. It is not denied that under certain conditions protein may be the sole source of muscular energy.

Some observations on common purslane, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp. 84, 85*).—Purslane (*Portulaca oleracea*) was found to have the following percentage composition (in dry matter): Protein 30.43, fat 2.61, nitrogen-free extract 34.24, crude fiber 10.12, and ash 22.60. The length of time which the plants would retain water was tested. On July 11 a quantity of purslane was suspended in a room the temperature of which rose daily to 90° F.

> "In the 19 days' trial the plants had lost 45.74 per cent of water out of a total of 91 67 which they contained; no observation was made between July 30 and September 5, when some leaves were yet green, while the plants had developed blossoms and ripened an abundance of seeds."

Feeding cotton seed, cotton-seed meal, and corn to beef steers, E. R. LLOYD (*Mississippi Sta. Bul. 60, pp. 17–22, 28–32*).—The feeding value of cotton seed, cotton seed meal, and corn-and-cob meal was tested with 3 lots of 2 young steers each, 9 months old at the beginning of the trial. The test proper began December 5, 1898, and covered 4 periods of 30 days each. The grain mixture varied in different periods. The corn-and cob meal was fed alone or in combination with wheat bran, and the cotton seed and meal were both fed with wheat bran and with corn-and cob meal. All the steers were fed Johnson grass hay in the first 3 periods, and alfalfa hay in the fourth period.

Taking the average of the first 3 periods, the author concludes that a pound of cotton-seed meal is equivalent to 1.6 lbs. of cotton seed or 1.92 lbs. of corn, and that a pound of cotton seed is equivalent to 1.22 lbs. of corn. In the fourth period fair gains were made by lots 1 and 2, while there was a slight loss in lot 3 which is accounted for, in the author's opinion, by the condition of one of the steers. The best gains in this period were made with lot 1, "which indicates that the alfalfa hay made a better balanced ration with corn-and-cob meal than did the grass hay."

In discussing the fertilizer constituents recovered in the manure (see also p. 1022), W. R. Perkins and E. B. Ferris record data for determining the balance of income and outgo of nitrogen, phosphoric acid, and potash. The test covered 1 week and included one steer from each of the 3 lots. The results follow:

Balance of income and outgo of nitrogen, phosphoric acid, and potash

Food eaten	Nitrogen				Phosphoric acid				Potash			
	In food	In urine	In feces	Gain	In food	In urine	In feces	Gain	In food	In urine	In feces	Gain
	Oz	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*	*Oz*
Steer 1, 448 oz Johnson grass hay, 784 oz corn and cob meal	12.835	3.510	7.817	1.508	7.290	2.028	3.928	1.334	10.506	7.722	2.301	0.483
Steer 2, 448 oz Johnson grass hay, 448 oz corn and cob meal 224 oz cotton seed meal ...	24.102	10.223	9.748	4.131	13.215	2.850	8.711	1.654	13.619	8.552	3.733	1.334
Steer 3, 448 oz Johnson grass hay, 448 oz corn and cob meal, 336 oz cotton seed	19.756	7.033	9.243	3.480	9.944	1.529	7.378	1.037	13.025	7.415	4.540	1.070

From the data recorded it would be possible to compute the digestibility of the dry matter, protein, phosphoric acid, and potash in the three rations.

Value of cotton seed to the farmer, W. L. HUTCHINSON (*Mississippi Sta. Bul. 60, pp. 1–3*).—The author summarizes the results of tests on the value of cotton seed reported in this bulletin and notes the value of cotton seed for manure and for feeding.

> "The present disposition of the cotton seed crop secures to the farmer a very small part of its real value and must of necessity give place to a practice that will secure to the farmer the maximum benefit which he may derive from this product.
>
> "The time will come when the southern farmer will realize that the fertilizing value in cotton seed must stay on the farm to maintain its fertility and productiveness. . . .
>
> "[It is probable that in the future] there will be a small oil mill at each ginnery and oil and lint will be the only products of the cotton crop sent to market. The southern farmer, however, need not wait for oil mills. He may get the full value of his cotton seed by a judicious system of feeding, accompanied by the most careful saving and proper use of the manure."

Feeding experiments, G. E. MORROW and J. H. BONE (*Oklahoma Sta. Rpt. 1899, pp. 18–32, figs. 3*).—Feeding experiments made from 1896 to 1899 with steers, pigs, mules, horses, sheep, and lambs are briefly reported, the principal object being to test feeding stuffs which can be readily grown under local conditions, and which may be prepared at small cost.

Tests with steers (pp. 24–27).—In 1898–99 Kafir corn and maize were compared with 5 lots of 2 steers each. The test covered 24 weeks. Lot 1 was fed Kafir corn meal; lots 2 and 5, maize meal; lot 3, maize meal and Kafir corn meal, 1:1; all the lots being given a full ration. Lot 4 was fed approximately 1 lb. of Kafir corn meal per hundred pounds live weight for 5 weeks, and afterwards a full ration of the same grain. The average daily gain of the 5 lots in the first 12 weeks of the test was 2.32, 2.75, 2.64, 1.63, and 2.80 lbs., respectively. In the second 12 weeks the corresponding gains were 2.50, 1.63, 1.90, 1.75, and 2.68 lbs., respectively.

In 1897–98, a test was made with 2 lots of 5 steers each. It was divided into 2 periods of 4 and 5 weeks, respectively, with an interval of 2 weeks between. In the first period lot 1 was fed Kafir corn meal and lot 2 corn meal. In the second period, the conditions were reversed. In the first period the average daily gain of the steers fed Kafir corn meal was 3.64 lbs.; of those fed corn meal, 2.21 lbs. In the second period the steers fed Kafir corn meal gained on an average 1.42 lbs. per day, and those fed corn meal 1.69 lbs.

In 1896–97, a test covering 23 weeks was made with 5 lots of 4 steers each. Lot 1 was fed from racks and troughs in a well protected yard. The other lots were fed in box stalls. During the day they had the run of a large lot. The average daily gain of the steers in lot 1 was 2.19 lbs., while the average daily gains of the lots fed in box stalls ranged from 1.63 to 1.84 lbs. The effect of dehorning was observed with 11 of the steers. There was an apparent loss of weight from dehorning, but it is stated that none of the dehorned steers were off feed at any time.

Brief statements are made concerning cotton seed as a feed for cattle, moderate quantities (about 4 lbs. per day) in connection with Kafir corn having given good results. No injury following the use of this feeding stuff has been observed. The gains made by cattle on pasture are briefly spoken of, as well as the marked variations which have been observed in the gains made by different cattle.

Tests with pigs (pp. 27–30).—The value of alfalfa pasturage, with and without grain, was tested with 2 lots of 4 pigs each. In 8 weeks the total gain of the pigs fed alfalfa alone was 68 lbs.; of those fed alfalfa and grain (Kafir corn meal and shelled corn), 324 lbs.

The weight of pigs at birth and the gains made by a number of litters were recorded. The average weight of the pigs in 9 litters at birth ranged from 2.25 to 3.07 lbs., the mean being 2.65 lbs. Gains made by sows fed Kafir corn meal and by pigs following cattle fed Kafir corn on the ear or unground shelled corn were also recorded, as well as the gains made by pigs fed different forage crops. These included sugar beets, cowpeas, sorghum, sweet potatoes, and peanuts. Five trials of the comparative value of Kafir corn and maize for pigs are briefly reported. The average results follow:

Kafir corn and maize for pigs.

No. of pigs.	Ration.	Time.	Average weight at beginning.	Average daily gain.	Grain eaten per pound of gain.
		Days.	*Pounds.*	*Pounds.*	*Pounds.*
6	Kafir corn	42	135	1.11	6.65
8	Kafir corn meal	24	220	1.80	5.60
2	First period corn on ear	35	125	1.53	4.94
	Second period Kafir corn meal	14	178	1.00	9.21
4	First period Kafir corn meal	35	105	1.21	5.08
	Second period. Shelled maize soaked	14	147	.53	7.07
	Third period Shelled maize, soaked, and alfalfa fodder.	28	154	1.25	3.65
4	Corn meal and poor quality ground wheat, 1:2.2	30	170	1.50	5.44

"Alfalfa is excellent as pasture for hogs. Pigs will make some gain with no other food; excellent gains when fed grain while on the alfalfa. Continuous pasturing will injure and may destroy the alfalfa. With rare exceptions, alfalfa should not be pastured the year it is sown. Sorghum also makes a fair pasture for hogs. Sowing cowpeas, planting peanuts or sweet potatoes and allowing hogs to harvest the crop, giving them some grain in addition, reduces the cost of pork production. Sugar beets are much relished by any class of stock. The greater cost of growing them as compared with other crops makes it doubtful if they are an economical crop when used in large quantities."

Tests with horses and mules (p. 31).—Brief statements are made concerning the amount and cost of food consumed, the amount of water drank, and the work performed by horses and mules at the station. When fed Kafir corn and maize, each rated at 20 cts. per bushel, oats at 25 cts. per bushel, and bran at 25 cts. per hundredweight, the average cost of a day's labor was estimated to be 17 cts. On an average a pair of mules and a pair of horses, each weighing 2,130 lbs., drank 107 lbs. of water per day while at moderate work. When idle, during hot summer weather, a pair of mules drank on an average 113 lbs. of water daily and on one day 350 lbs. were drank.

Tests with sheep (p. 32).—Kafir corn heads with prairie grass hay and corn stover was fed to 16 grade Shropshire wether lambs for 13 weeks in the winter of 1898. They remained in good condition and gained a little over ¼ lb. per head per day, consuming a total of 1,624 lbs. of Kafir corn heads.

From all the tests the following conclusions regarding Kafir corn were drawn:

> "Kafir corn is a healthful, palatable, and nutritious food, but its feeding value is somewhat less than that of corn. As shown both by feed lot trials and by digestion experiments, there is a great loss in feeding this grain unthreshed to cattle—in some cases of 60 per cent, but hogs will utilize most of this waste. There is little difference in the waste whether the grain is fed unthreshed or threshed. In some cases, at least, the loss is greater when soaked grain is fed than when it is fed dry. In some trials steers fed Kafir corn meal made better gains for a long time than did those fed corn meal, but this was not true in any extended period. Hogs digest the unground grain better than do cattle. In general, hogs have made gains from four-fifths to five-sixths as great when fed on Kafir as when fed corn. Sheep seem to digest Kafir better than any other class of farm animals.
>
> "Kafir stover apparently has practically the same feeding value as corn stover, and often is in better condition. Running the entire stalk through a threshing machine puts the stover in excellent condition. Alfalfa is the best hay for either horses, cattle, or sheep, and is a help to hogs during winter. The value of cowpea and soy bean hay is underestimated by most Oklahoma farmers. No larger gains have been made by cattle at the station than when cowpea hay was their only rough forage.
>
> "Shelter should be provided for all classes of stock, but expensive buildings and stall feeding of cattle are not necessary. While there is, occasionally, extreme cold, ordinarily protection from rain and cold winds by means of simple sheds is all that is needed for the comfort of farm animals"

Reports on experiments in sheep feeding on turnips, Perthshire, J. W. PATERSON (*Glasgow and West of Scotland Tech. Col., Agr. Dept. Rpts., 1898, pp. 110–119*).—A test was carried on by T. Wylie, of Stockbridge, Dumblane, with 40 sheep, divided into 4 equal lots. They were folded in separate pens on a stubble field. The test began December 19 and covered 93 days. Turnips and hay were fed alone and with the addition of oats and linseed cake and of peas, lentils, and maize. During the latter part of the experiment swedes were substituted for turnips. The principal deductions follow:

> "Turnips and hay alone can not be profitably used in feeding sheep. The turnips should be limited and the deficit made good with concentrated foods. These foods should be rich in flesh formers. Linseed cake should form the larger part in a mixture with oats. Maize may be employed on account of its cheapness, if due regard be had to narrowing the ratio. With a fixed amount of food, most increase is made the first weeks, and the ration should be increased as fattening progresses."

A test made by J. Sterling at Mains of Kippendavie is briefly reported. Three lots of 10 sheep each were fed the same grain rations as in the above test in addition to turnips and hay. The results confirm those of the test at Stockbridge.

An attempt to establish a relationship between the manurial treatment of farm produce and its feeding properties, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 7 (1898), pp. 53–63, 113–115*).—In the winter of 1898 a test was made with sheep of the feeding value of turnips and hay which had been grown on plats differently fertilized. No definite conclusions were drawn.

A similar experiment was made in the winter of 1898–99 with 18 lots of sheep, the lots containing 5 or 6 sheep each. The test covered 14 weeks. The feeding stuffs tested were turnips, hay, and oat hay. These crops had been fertilized with bone meal, nitrate of soda and superphosphate, sulphate of ammonia and superphosphate in different proportions, and superphosphate alone. In addition to turnips, hay, or oat hay, all the sheep were given a small amount of oats (⅓ to ½ lb. per head daily). The average gains in the 14 weeks of the test ranged from 12.6 to 20.9 lbs. The principal conclusions follow: Compared with hay as a standard, the bone meal produced the most nutritious feed, but, in the author's opinion, this factor does not compensate for the lower yield. Nitrate of soda and sulphate of ammonia gave the same yield of hay and produced practically the same gains in live weight. A double amount of sulphate of ammonia increased the hay crop, but diminished the gains made by the sheep.

The effect of feeding sheep under cover, out of doors, on grass pasture and on turnip land was also discussed. When fed under cover, the average gains in 14 weeks was 20.9 lbs.; when fed out of doors, 20 lbs.; when hurdled on turnip land, 18.9 lbs., and when on grass pasture, 16.6 lbs.

The advantages of the different methods of handling sheep are discussed at some length.

Feeding cotton seed to hogs, E. R. LLOYD (*Mississippi Sta. Bul. 60, pp. 26, 27*).—Two tests of the value of raw and cooked cotton-seed meal for hogs are briefly reported. The first test, which covered 12 weeks, was made with 4 lots of 2 Berkshire hogs each. Cooked cotton seed and raw and cooked cotton-seed meal were fed with corn meal or whole corn to different lots. No figures are recorded for gains in weight, etc.

"The gain made by the lots was neither satisfactory nor profitable. The hogs began to die first in the lot getting raw cotton-seed meal. The first hog died at the end of the fourth week, and at the end of the eighth week the remaining hogs in the same lot died. While the hogs getting the cooked seed and meal did not die, some were very sick and refused to eat and would get better and begin eating again after being allowed to run in an oat and clover patch for several days. After the fourth week most of the hogs began to lose flesh, and after the sixth or eighth week none of the lots made gains."

In the second test 23 pigs 4 months old were fed for 46 days a ration consisting of cooked cotton seed, corn meal, shorts, and skim milk. During the first 2 weeks there was an average daily gain of 1 lb. Afterwards the gains were small.

"The pigs continued to eat with great relish, leaving no waste. At the end of 40 days the pigs began to die, and when the experiment closed 4 pigs had died and several others were sick, but were turned into a clover lot and were apparently well in a week. Some of those pigs were kept until grown and put on feed to fatten for market. The cotton-seed pigs were poor feeders, and were never gotten in good condition. . . .

"Until some method is devised by which the poisonous element in the feed can be cheaply and completely extracted, cotton seed and its products can not be considered as a feed for hogs."

Poultry experiments during the year 1898–99, F. E. EMERY (*North Carolina Sta. Bul. 167, pp. 391–416*).—In this bulletin, which summarizes the work of the poultry department of the station for 1 year, tests of the comparative value of different crosses and breeds, the advisability of selling eggs by weight, and "feeding flavor into eggs" are reported.

Class vs. class and breed vs. breed; rations for hens and methods of feeding (pp. 391–402).—A number of breeds of the Mediterranean class (Black Minorcas and Single-comb Brown Leghorns), the American class (Barred Plymouth Rocks, White Plymouth Rocks, and Silver-laced Wyandottes), and the Asiatic class (Buff Cochins, Black Langshans, and Light Brahmas) were compared, each class including both pullets and hens. All the lots were fed bran, wheat middlings, and corn meal, 4:2:1, in the morning, wet up with steamed crimson clover, and usually cut fresh bone. In the afternoon different whole grains, including oats, wheat screenings, corn, and cracked corn, were fed alone and in combination. The composition of the different feeding stuffs is reported. The financial statements are based on corn and corn meal at 55 cts. per bushel; crimson-clover hay at 75 cts., green bone and wheat middlings each $1, oats $1.40 to $1.60, wheat bran 90 cts., and wheat screenings 80 cts. per hundred pounds; and eggs at 13½ cts. per dozen.

The results comparing the different classes of chickens are summarized as follows:

Results of tests with different classes of hens.

	Eggs laid per hen per month	Cost of production per month.	Maximum monthly profit above cost of food.	
			All eggs rated at 13 5 cts per dozen	Eggs rated at 13 5 cts per dozen of 17 5 oz
		Cents	*Per cent.*	*Per cent.*
American class	11.60	8 94	38 26	199.35
Asiatic class	11.30	10 68	11 05	168.35
Mediterranean class	11.04	6.24	87.50	147.12

The different breeds are compared at some length.

> "The leading breeds in this comparison are Brown Leghorn, Barred Plymouth Rock (counting the late hatch hens only), Black Langshan, and White Wyandotte. If Silver-laced Wyandotte were represented by mature fowls as good in proportion as the pullets they would stand second best in rank in economy of production.
>
> "As far as this record goes it shows that for high production, weight of eggs produced, as well as for economy in production, pullets far outstrip hens. Young vigorous stock is the best stock to keep for profit."

Should eggs sell by weight? (pp. 403-405).—On the basis of the above tests the desirability of selling eggs by weight is discussed.

> "The heaviest eggs are from the ducks. These weigh nearly 2¼ lbs. per dozen. The average weights of the ducks is but 4.1 lbs. The Light Brahma hens lay the largest eggs, and these are 1¾ lbs. per dozen. The lightest eggs are from Leghorn pullets, a little under 1⅛ lbs. per dozen."

At the same price per dozen, if the Leghorn eggs are worth 13½ cts. per dozen or 12 cts. per pound, the eggs of the other breeds would be actually worth from 16.3 cts. for the Single-comb Brown Leghorns to 21.6 cts. for the Light Brahma; or from 20.7 to 60 per cent in excess of their market value. The eggs of the Pekin ducks would be worth 26.7 cts., or 97.8 per cent above their market value.

Feeding flavor into eggs (pp. 505, 506).—Chopped wild onion tops and bulbs were mixed with the feed of 12 hens of different breeds. After the onion flavor was noticeable in the eggs, the onions were discontinued. The principle conclusions of the test follow:

> "Flavors can be fed into eggs. Therefore it appears that to insure fine-flavored eggs it is necessary to restrict the runs enough so no considerable amount of the food can be of such a character as to yield ill-flavored eggs. It is probable that the flavor caused by eating onions is not noticeable after a week's abstinence."

Experiments with chickens, E. P. NILES (*Virginia Sta. Bul. 96, pp. 6*).—Brief statements are made concerning the breeds and crosses of chickens raised at the station.

> "[White-crested Black Polish crossed with common barnyard fowls] produced a most excellent chicken. The crest was not entirely lost but was reduced about one-half in size and was invariably black. The cross was of medium size, rather long-legged, wild, and good rovers. The flesh had a gamy flavor, was fine grained, and, we should say, as a table fowl could not be excelled. . . . [From the Partridge Cochin crossed] on the common fowl we have got good results. The product of the cross varies in color but is much inclined to buff and many of the characteristic points of the Cochin are retained. We do not know, however, that the laying qualities are improved. Considering the cross from the standpoint of the 'scrub,' we consider it a very desirable one. . . .
>
> "During the present year we have tried crossing the White Indian Game on the White Cochin and the results have been most excellent. One dozen White Cochin hens were mated with a White Indian Game rooster in the spring, and as the mating was late no early chicks were hatched. In due time, however, the eggs were found to be fertile and hatched excellently, almost every egg putting forth a strong, healthy chick. . . .
>
> "For the table [the crosses] are unsurpassed. The meat is fine in texture, of a gamy flavor, and not dry as is the flesh of many fowls; breast full and plump and

legs and thighs large. The chicks are extremely hardy, scarcely one being lost after hatching. They require but little attention, are good rangers, and, on the farm, would forage for their own living under ordinary circumstances."

Bread from a mixture of flour and corn meal or corn flour, W. O. ATWATER (*New York State Lunacy Com. Rpt 1897–98, I, pp. 379–381*).—The composition of 2 samples is reported. One sample, apparently made of 75 per cent of wheat flour and 25 per cent of yellow corn meal, had the following composition: Water 32.2 per cent, protein 9.7, fat 2.0, carbohydrates 54.8, and ash 1.3. Another sample, made apparently from a mixture of 75 per cent of wheat flour and 25 per cent of white corn meal, contained: Water 29.7 per cent, protein 9.4, fat 2.7, carbohydrates 56.8, and ash 1.4. In a discussion of the report the successful use for bread making of white corn flour mixed with wheat flour at a number of the New York State hospitals for the insane is noted.

The place of sugar in the diet, A. DROUINEAU (*Med. Modern., 9 (1898), No 91, pp. 721, 722*).—A discussion and review of recent work on this subject.

Sugar: Its value as a nutrient and its relation to muscular work, A. DROUINEAU (*Gaz. Hôp., 72 (1899), No. 102, pp. 937–945*).—A critical review of the subject, with many citations.

Nutrition experiments in the maneuvers of 1898, LEISTIKOW (*Deut. Mil. Ztschr., 28 (1899), No. 3, pp. 129–141*).—The author reports tests on the value of tropon, maté, and sugar in the ration of soldiers during the maneuvers. The tests are briefly discussed. Tropon had apparently no especially beneficial effect. Sugar was readily eaten. It checked hunger and thirst, but caused no gain in weight or apparent effect on the muscular work performed. Maté was found to be a satisfactory beverage.

Japanese edible fungi, P. HENNINGS (*Notizbl. K. Bot. Garten u. Mus., Berlin, 2 (1899), No. 20, pp. 385, 386*).—Five sorts of edible fungi are described. An abundance of material enabled the author to amplify or correct some of the statements made by J. Schröter.[1]

Examination of commercial vinegars sold in the State at retail, P. SCHWEITZER (*Missouri Sta. Rpt. 1898, pp 85, 86*).—Eleven samples of vinegar were examined. "Four are either known or pronounced to be cider vinegars, while the other 7, though sold under this name, are nothing but malt or alcohol vinegars."

Swiss food book (*Schweitzerischer Lebensmittelbuch. Bern: Neukomm & Zimmerman, 1899, pp. VII+222; rev. in Oesterr. Chem. Ztg., 2 (1899), No. 20, pp. 527, 528*).—This volume contains the Swiss official methods for the examination of foods and condiments.

The composition and feeding value of frozen wheat, L. FOSTER (*Utah Sta. Press Bul., pp. 3*).—The composition of high-grade frozen wheat, low-grade frozen wheat, and first and second grade wheat screenings, is reported, the average composition of ordinary wheat being quoted for purposes of comparison. On the basis of tests at the Canadian Experimental Farms (E. S. R., 6, pp. 452, 466), the value of frozen wheat is discussed.

Feeding animals wheat (*Semaine Agr., 19 (1899), No. 972, pp. 420, 421; 20 (1900), No. 974, pp. 13, 14*).—This general discussion is made up of quotations from articles by L. Grandeau and Couteaux, which appeared in the *Temps*.

Investigations on the composition of French and foreign soft wheats, A. GIRARD and M. FLEURENT (*Bul. Min. Agr. [France], 18 (1899), No. 6, pp. 1032–1154, figs. 2, dgm. 1*).—The composition of a large number of samples of French and foreign wheats is reported. The analytical methods followed are described.

Nutritive value of beet pulp (*Semaine Agr., 19 (1899), No. 972, p. 419*).—The composition of ensiled beet pulp (both from maceration and diffusion process) is quoted from Sydersky, and a ration is suggested for cattle and sheep, of which this forms a part. The work of other investigators is cited.

---

[1] Gartenflora, 35 (1886), pp. 101, 134.

Composition of cowpeas and millet grown on college farm, P. Schweitzer (*Missouri Sta. Rpt. 1898, p. 84*).—The composition of cowpeas cut when the pods were beginning to ripen and millet cut in the dough stage is reported.

Cowpea vine hay, A. M. Soule (*Tennessee Sta. Press Bul. 12, p. 1*).—The feeding value of cowpeas is discussed and the digestibility of this feeding stuff compared with that of other standard crops.

Analyses of new dairy foods, P. Schweitzer (*Missouri Sta. Rpt. 1898, pp. 111, 112*).—Tabulated analyses are given of 5 samples of by-products of oat-meal mills and glucose factories used extensively by dairymen in the vicinity of St. Louis.

Ensilage, F. Gillanders (*New Zealand Dept. Agr Rpt. 1899, pp. 168, 169, pl. 1*)—The manufacture at the Momohaki Experiment Station of stack silage is described and its successful feeding to steers reported. According to the author, when building the stack a piece of 1¼ or 1½ in. galvanized-iron pipe should be inserted horizontally. An ordinary thermometer can then be used to ascertain the temperature of the interior of the stack.

"Sweet ensilage is made at a temperature ranging from 125 to 160° F. A temperature higher than 160° should be avoided. Sour ensilage is made at a low temperature, ranging from 85 to 125°. Sour ensilage is considered the best for milk production, sweet for fattening. The temperature is regulated by the pressure applied to the stack or silo. The greater the pressure, the less the temperature."

Feeding corn and Kafir, J. Fields (*Oklahoma Sta. Rpt. 1899, pp. 71-74*).—Results obtained at the Kansas Station with Kafir corn are quoted as well as the principal conclusions obtained in digestion experiments with Kafir corn at the Oklahoma Station. These were abstracted from another publication (E. S. R., 11, p. 277). The composition of Kafir corn before and after passing through the digestive tract of steers is also reported. The author points out that the small hard grains were but slightly affected by the digestive juices. The author also suggests a system of nomenclature, based on current usage, for Kafir corn and Kafir corn products.

The formation of fat in the animal body under the influence of phosphorus, J. Athanasiu (*Arch. Physiol. [Pflüger], 74 (1899), No. 11-12, pp. 511-560*).—Experimental work with discussion and an extended bibliography of the subject is given. This work is of interest since it bears on the question of the formation of fat from protein.

On the formation of sugar from protein (glycogen formation without glycogen) R. Lépine (*Semaine Med., 19 (1899), No. 972, pp. 417-419*).—A critical review of the subject with many citations and references to the literature.

Differences in the ultimate composition and the experimental and calculated thermal values of feed and feces, P. Schweitzer (*Missouri Sta. Rpt. 1898, pp. 101, 102*).—The elementary composition and fuel value of timothy hay and a number of samples of feces from steers fed this hay were determined.

A proposal to establish a meter-gram-day system of notation for the unification of physiological measurements, J. de Rey-Pailhade (*Projet d'établissement d'un système metre-gramme-jour pour l'unification des mesures physiologiques. Toulouse: Lagarde & Sebille, 1899, pp. 8*).—In accordance with a recommendation made at the congress of physiologists in Cambridge, England, in 1898, the author has elaborated a system for the decimal notation of time. The suggested units are a centième, equal to 14 minutes and 34 seconds; a millième, equal to 1 minute and 26.4 seconds, and a cent-millième, equal to 0.864 second. Examples are given of the use of these units in expressing physiological observations which have to do with the expressions of values for a unit of time, such as food consumed, oxygen consumed and liberated, etc. A simple table is given for recalculating ordinary measurements of time to the proposed system.

Experiment on rearing four kinds of cattle at Cockle Park, W. Somerville (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 7 (1898), pp. 65-67 and 116*).—The results obtained in crossing Polled Angus, Galloway, and West Highland heifers to a Shorthorn bull are reported in some detail. In the author's opinion practically the same results were obtained with Shorthorn and Galloway crosses; the Highland cross ranked next, and the least satisfactory results were obtained with the Polled Angus cross.

Calf rearing, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 7 (1898), pp. 73, 74*).—The following is recommended as a satisfactory feed for young calves: Flour, 1 part; ground flaxseed, 2 parts; ground linseed cake, 3 parts. Two and a half pounds of this mixture is considered a day's allowance for a calf. According to the author, it should be scalded with boiling water and sufficient water added to make 2 gal. It should be fed in 3 meals, a little salt and sugar being added before feeding. It is recommended that "it should gradually be made to take the place of new milk after the first fortnight."

Calf rearing, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 8 (1899), p. 95*).—Brief statements are made concerning the successful use of boiled linseed oil and codliver oil as a supplement to skim milk in feeding calves.

Raising young cattle, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 8 (1899), pp. 96, 97*).—A brief note on the cost of keeping 2 bullocks from birth until 17 months old and 4 heifer calves from birth until 23½ months old.

Sheep breeding experiment, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 7 (1898), pp. 51–53, 112*).—In 1897 a breeding experiment was made with 30 Cheviot, 30 Black-faced, and 30 mule ewes. The Cheviots were bred to a Border-Leicester, the Black-faced to an Oxford, and the mules to a Suffolk ram. "The Cheviot has proved the most prolific and the Black-faced least so, but perhaps just because most prolific, the average weight of the Cheviot crosses is the lowest of the three. In this respect the mule crosses came out best."

Sheep feeding, W. SOMERVILLE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 8 (1899), pp. 94, 95*).—The value of turnips in addition to pasture for sheep was tested for 8 weeks by W. T. Lawrence at Newton Rigg Penrith with 2 lots of 15 crossbred sheep. Both lots received a basal ration of ¼ lb. of linseed cake, and ¼ lb. of oats per head daily, with hay *ad libitum*. In addition lot 1 was fed turnips and lot 2 was pastured. The average weight of the sheep in the 2 lots at the beginning of the test was 98 lbs. and 102 lbs., respectively. Lot 1 made a total gain of 208 lbs. while lot 2 lost 30 lbs. The 2 lots consumed 410 and 300 lbs. of hay, respectively.

The production of crosses and mongrels of the Yorkshire and Casertana races of swine, S. BALDASSARRE (*Ann. Regia Scuola Superiore Agr. Portici, 2. ser., 1 (1899), pp. 1–204, figs. 63*).—This paper contains a historical account of the Yorkshire and Casertana races of swine, together with an elaborate discussion of experiments conducted in producing crosses and mongrels between these races.

The results of the author's experiments are summarized under the following heads: The effects of crossing upon the duration of gestation; upon fecundity; upon the growth, weight, and conformation of the body; upon the pigmentation of the skin; and upon the characters of the skull.

The Penycuik experiments, J. C. EWART (*London: Adam & Charles Black, 1899, pp. XCIII + 177, figs. 34*).—The author describes his experiments in crossing a zebra with mares, and discusses them in their bearing upon the theory of telegony and reversion. In an extended introduction the general subject is discussed at considerable length.

DAIRY FARMING—DAIRYING.

The amount of food consumed by a cow producing a large quantity of milk and butter, W. B. CADY (*Missouri Sta. Rpt. 1898, pp. 113–123*).—A record was kept of the amount of food consumed by a Holstein cow during a 7-day milk and butter test. The cow weighed 1,150 lbs. and had been fresh 57 days at the beginning of the test. During the 7 days the cow consumed daily 15 lbs. of wheat bran, 3 lbs. of old-process linseed meal, 13.31 lbs. of ground corn and oats, and an average of 39.24 lbs. of corn silage and 7.57 lbs. of clover hay.

Analyses were made of the feeding stuffs, and a table shows the amount of total and digestible nutrients consumed.

The food consumed during the test was valued at $1.78. The total yield of milk was 420.86 lbs., containing 16.32 lbs. of fat, calculated equivalent to 20.4 lbs. of butter. With milk at $1.05 per 100 lbs. or butter at 20 cts. per pound, the net profit is estimated at $2.64 or $2.30, respectively. A daily milk record of the cow for 55 days previous to the test is also given.

A test of another cow, in which, however, the exact amount of food consumed was not determined, showed a net profit in 7 days of $2.70 or $1.40, corresponding respectively to the prices of milk and butter given above. "It is very clear that even under this high feeding, in this case at least, cows of great milk-producing capacity were able to return a good net profit."

Feeding experiments and milk records, F. E. EMERY and J. M. JOHNSON (*North Carolina Sta. Bul. 169, pp. 20*).—Tabulated data showing the amount of food consumed and the yield of milk and fat are given, with comments, for 8 feeding experiments, conducted during 1897 and 1898. The tests were made with from 1 to 5 cows, and extended over 3 or 4 periods of 10 days each. The yields of milk and fat were averaged from the records of the last 4 days of each period. Corn silage was fed with all the rations mentioned below.

Wheat bran and rice bran were compared in rations containing, in addition, corn bran and cotton-seed meal. The trial included 3 cows. The rice-bran ration was fed during the first and fourth periods and the wheat-bran ration during the second and third periods of the test. A greater yield of milk and fat was obtained on the rice-bran ration.

In a second test wheat bran alone was fed to 2 cows during the first and third periods and rice bran alone during the second period. The conclusion is drawn that rice bran with silage is insufficient to make a properly balanced ration for a milch cow.

A test with 2 cows was made of wheat bran vs. rice bran in combination with cotton-seed meal. The wheat-bran ration was fed during the first and fourth periods and the rice-bran ration during the second and third. A greater yield of milk was obtained on the wheat-bran ration. A slightly larger yield of fat on the rice-bran ration is considered within the limit of error.

Wheat bran alone and a mixture of equal parts of wheat bran and wheat middlings were each fed to 2 cows during 2 periods. "This experiment points to a decided gain in yields by the use of wheat middlings in the ration when fed at the rate of 50 per cent."

A ration of wheat bran and cowpea meal, 2:1, in connection with silage, was compared with a similar ration containing about 3 lbs. of millet hay in addition. The first ration was fed to 4 cows during the first and fourth periods, and the millet-hay ration during the second and third. Four cows were used in the test. On the whole, the effect of the addition of millet hay was considered scarcely perceptible. During the fifth and sixth periods of the test cowpea meal and cotton-seed meal, fed in connection with wheat bran and silage, were compared, with results favorable to cotton-seed meal. The addition of green crimson clover to the cotton-seed meal ration during a following period showed no very marked results.

Comparisons were made of mixtures of (1) wheat bran and cotton-seed meal, 2:1, with rice bran and cotton-seed meal, 2:1, and (2) wheat bran and cotton-seed meal, 2:1, with wheat middlings and cotton-seed meal, 2:1. Each test was made with 1 cow and covered 4 periods. The tests indicated no marked difference in the feeding value of wheat bran as compared with rice bran and wheat bran as compared with wheat middlings when fed with one-half their weight of cotton-seed meal.

A mixture of wheat bran and cotton-seed meal 2:1, was compared with wheat bran alone. Two cows were used and the test covered 4 periods. During the first and fourth periods the grain mixture was fed, and during the second and third the bran alone. The results showed a difference of 4.75 per cent for milk production and 13.51 per cent for fat production in favor of the mixture of wheat bran and cotton-seed meal over wheat bran alone.

The record of the station herd from 1891 to 1899 is reviewed. The largest yield of milk was obtained in 1896, and averaged 5,672.6 lbs. for 7 cows.

Feeding cotton seed, cotton-seed meal, and corn to dairy cows, J. S. Moore (*Mississippi Sta. Bul. 60, pp. 4–13*).—Tests were conducted during two winters to determine the relative feeding value for dairy cows of cotton seed, cotton-seed meal, and corn-and-cob meal. Each test included 2 lots of 4 cows each and lasted 4 weeks. The 2 lots in each case received the same basal ration of peavine hay, silage, and wheat bran. The work is reported in tabular form and conclusions are drawn.

Three tests were made comparing respectively 3, 3½, and 4 lbs. of cotton-seed meal with 6 lbs. of cotton seed. Cows fed the cotton seed gave a better yield of milk than cows fed 3 lbs. of cotton-seed meal, nearly the same as cows fed 3½ lbs., and a decidedly lower yield than cows fed 4 lbs. of the meal.

In 2 tests a comparison was made of cotton seed and corn-and-cob meal. Lot 1 in the first test was fed 6 lbs. of corn-and-cob meal for 3 weeks and 8 lbs. for the remaining week of the test. Lot 1 in the second test was fed 8 lbs. of corn-and-cob meal. Lot 2 in both tests received 6 lbs. of cotton seed. In neither test was the yield of milk from the cows fed corn-and-cob meal equal to that from the cows fed cotton seed.

Rations containing 3 and 3½ lbs. of cotton-seed meal and 6 and 8 lbs. of corn-and-cob meal, respectively, were compared in 3 tests. The ration containing 3 lbs. of cotton-seed meal gave the lowest yield of milk and the one containing 3½ lbs. the highest. A larger yield of milk was obtained from feeding 6 lbs. of corn-and-cob meal than from feeding 8 lbs. On the ration containing the larger quantity of meal the cows gained materially in weight with a decrease in milk flow.

The author summarizes the results obtained regarding the relative value of the different feeding stuffs as follows:

> "(1) One pound of cotton seed is equal to 1.17 lbs. of corn-and-cob meal (corn meal), or to 0.58 lb. of cotton-seed meal.
>
> "(2) One pound of cotton-seed meal is equal to 1.71 lbs. of cotton seed, or 2 lbs. of corn-and-cob meal.
>
> "(3) One pound of corn-and-cob meal is equal to 0.50 lb. of cotton-seed meal, or 0.85 lb. of cotton seed."

Influence of the feed on the quality of milk and butter, J. S. MOORE (*Mississippi Sta. Bul. 60, pp. 14–16*).—In the feeding experiments noted above determination by the Babcock tester showed no changes in the fat content of the milk that could be ascribed to the different feeding stuffs used.

The following statement is made relative to the effect of food on the butter fat:

> "The average melting point of butter made from cows fed 5 lbs. of cotton-seed meal a day, as determined by several tests made by this station, is 100.1° F., while that from cows fed corn meal and wheat bran as a grain ration is 96.8° F. The butter from the cotton-seed meal or cotton seed is therefore firmer and will stand shipment better during the summer months than will that made from cows receiving no cotton seed or meal."

In a study of the effect of food on the quality of butter the station herd was fed 2 weeks a ration containing 5 lbs. of cotton-seed meal, 10 lbs. of peavine hay, 20 lbs. of corn silage, and 4 lbs. of wheat bran. During a second period of 2 weeks 6 lbs. of cotton seed was substituted for the cotton-seed meal, and during a third period of the same length this was replaced by corn-and-cob meal.

The butter made from the milk obtained during the last 2 days of each experiment was scored by experts. The results are given by the author as follows:

> "The butter made from the herd when it was getting cotton seed scored 96 points out of a possible hundred, which was the same score as that made by the butter from the herd getting corn-and-cob meal. The score of the butter made from the

herd getting cotton-seed meal was 95½ points. There is such a slight difference between the scores that the quality is practically the same for the different feeds. The quality of the butter was not injured by feeding as much as 5 lbs. of cotton-seed meal or 6 lbs. of seed."

Feeding experiments with pumpkins for milch cows, O. MOMSEN (*Milch Ztg., 29 (1900), No. 1, pp. 6, 7*).—Pumpkins and mangel-wurzels in rations otherwise alike were compared in an experiment with one cow. The test covered 3 periods, the first extending over several weeks and the second and third lasting 8 days each. The pumpkins were fed during the second period. The yields of milk, fat, and total solids are given for each milking during the last 3 days of the different periods. On pumpkins the average daily yield of milk was lower, but the yield of fat was higher than during the other 2 periods. The percentage of solids as well as of fat was also higher in the second period. The test is considered as showing that pumpkins are a useful food for milch cows and that they produce more fat than the same quantity of mangel wurzels.

The relation of food to milk fat, L. ANDERSON (*New York Cornell Sta. Bul. 173, pp. 43, dgms. 6*).—The author summarizes 44 experiments by various investigators concerning the relation of food to the fat content of milk, and reports 2 experiments with rations having different nutritive ratios, and 1 with rations containing varying quantities of palm-nut meal. The 44 experiments are classified, in answer to the question as to whether the percentage of fat in the milk was apparently increased by the food, as follows:

Number of experiments in which the fat content was increased by feeding.

	Yes.	No.	A tendency to increase.
Feeding fat	4	8	1
Feeding protein and mixed foods	3	20	3
Feeding watery foods	......	2	....
Feeding molasses preparations	3	.....	....
Total	10	30	4

"Of the 4 experiments where the fat in the food increased the proportion of milk fat, one reports so great a reduction in the yield as to make such feeding unprofitable. The noted experiment of Soxhlet, whereby he increased the percentage of milk fat by feeding the cows oil emulsified in the drinking water (E. S. R., 8, p. 1016), has been repeated many times by other experimenters, but none of them, so far as we know, have reached a similar result. The protein foods which increased the percentage of fat were palm-nut meal and sugar meal The molasses preparations may owe their power to increase the fat content of milk to their rather abnormal character."

The first experiment reported by the author was conducted by J. M. Johnson and extended from November 6, 1895, to April 7, 1896. Three lots of 3 cows each were fed from 8 to 10 lbs. per day of grain mixtures composed of linseed meal and oat chop, with and without gluten feed and cotton-seed meal or corn meal, together with corn silage and clover hay for lots A and B, and corn silage and timothy hay for lot C. The grain mixture was constant for each lot. The nutritive ratios of the 3 rations were: Lot A, 1:4.5; lot B, 1:6; and lot C, 1:9.

The second experiment was conducted by the author and lasted from November 11, 1896, to April 13, 1897. With the exception of one cow the same lots were used as in the first experiment. The lots received 8 to 12 lbs. per day of grain mixtures composed of wheat bran and corn meal or cotton-seed meal, with and without gluten meal or linseed meal. The coarse fodder was, as before, corn silage with clover or timothy hay. The nutritive ratios were: Lot A, 1:4.3; lot B, 1:5.7; and lot C, 1:9.3. In both experiments each lot received mangel-wurzels in addition for a portion of the period.

Tables give the average weekly record of food consumed and milk and fat produced by each lot during the 2 experiments. The data are also shown by means of diagrams and are discussed. Omitting the first 2 weeks of each experiment, the average percentages of fat for periods of 4 weeks each for the 3 lots during the 2 experiments are shown in the following table:

Fat content of milk of cows fed narrow, medium, and wide rations.

	First experiment.			Second experiment.		
	Lot A, narrow ration.	Lot B, medium ration.	Lot C, wide ration	Lot A, narrow ration.	Lot B, medium ration.	Lot C, wide ration.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent.*
First four weeks	3.46	3.40	3.47	3.29	3.77	3.93
Second four weeks	3.29	3.14	3.32	3.24	3.44	3.85
Third four weeks	3.44	3.37	3.27	3.23	3.47	4.07
Fourth four weeks	3.54	3.55	3.47	3.28	3.49	4.07
Fifth four weeks	3.68	3.65	3.68	3.34	3.56	....

"In the first experiment there was an increase from the beginning to the end with each lot of about two-tenths of one per cent of fat. In the second experiment this increase was about one-tenth of one per cent. . . .

"Taking both experiments into account, it would seem that the medium ration had a more favorable influence upon the continued production of milk and total butter fat than either the wide or narrow rations. Yet, if individual cases are considered, we find Belva 2d, on the narrow ration, holding out in her milk flow during both years as well as, or better than, any of the cows on the medium ration."

The effect of the palm-nut meal upon the percentage of fat in milk was studied in a trial conducted by G. N. Lauman. The experiment included 2 lots of 3 cows each and lasted 2 weeks. In addition to corn silage and hay, lot 1 was fed a grain mixture of palm-nut meal, gluten feed, and wheat bran, 2:2:1, and lot 2 a mixture of palm-nut meal, gluten feed, cotton-seed meal, and wheat bran, 4:3:2:1. The quantity fed lot 1 was constant throughout the experiment, while that fed lot 2 was increased several times. The nutritive ratio for lot 1 was 1:6; that for lot 2 varied from 1:5.16 to 1:4.64. A table gives the record of each cow during the experimental period and also for the 6 weeks preceding and following, when the grain mixture consisted of gluten

feed, cotton-seed meal, and wheat bran. 3:2:1. Averages are given in the following table:

Fat content of milk of individual cows on different rations.

	Lot 1.			Lot 2.		
	Gliata Netherland.	Gem Valentine.	Mollie	Mabel 2d	Ruby	Sadie.
Usual ration:	*Per cent.*	*Per cent.*	*Per cent.*	*Per cent*	*Per cent.*	*Per cent.*
First three weeks	3.06	5.28	2.98	3 94	....	3 21
Second three weeks	3.39	5.09	2.92	3 77	3.67	3.63
Palm-nut meal ration:						
First three weeks	3.32	5.80	3 27	4.32	3.26	3.28
Second three weeks	3 64	5.80	3 45	4 35	3.27	3.58
Usual ration:						
First three weeks	3 47	5.80	3.31	3.78	3.00	2.92
Second three weeks	....	5.84	3.30	4.03	3.14	3.48

"Taking everything into consideration, we do not feel warranted in saying that the feeding of palm-nut meal increased the percentage of fat in the milk. . . . There were variations in the fat content of the milk, but no more nor greater than when the food of the cows was unchanged."

The importance of bacterial tests in the sanitary supervision of milk supplies, M. O. LAIGHTON (*Science, n. ser., 11 (1900), No. 273, p. 461*).—In a paper read before the Society of American Bacteriologists, 1899, the author reported bacterial tests of the milk from 17 dairies in the vicinity of Montclair, N. J., for a period of 3 years ended June, 1899. Only the number of germs per cubic centimeter was determined. On the basis of the results for 3 years the dairies were grouped into 3 classes, according to the germ content of the milk, *i. e.*, (1) dairies having an average below 15,000 per cubic centimeter, (2) those between 40,000 and 70,000, and (3) those above 180,000. The dairies of class 1 were of the most improved type in which utmost cleanliness prevailed. Those of class 2 were poorly equipped, although the owners plainly endeavored to do their utmost with the crude means at hand, but were unable to provide proper sanitary appliances to aid them. Those of class 3 had neither good equipment nor good intentions, ignorance and indifference combining to produce an unwholesome product. As a result of the publication of the results from year to year, "no less than a dozen unworthy dairymen have found their business unprofitable. In addition to this several dairies have undergone a complete change in construction and in methods of production, and the supply as a whole has been raised to a high standard of purity."

Turbine Babcock testers, the cause of some incorrect tests, F. W. WOLL (*Hoard's Dairyman, 31 (1900), No. 4, pp. 74, 75*).—Chemical analysis of samples of milk preserved with potassium bichromate gave results uniformly from 0.1 to 0.3 per cent lower than the Babcock test. An investigation was made of the cause of this variation. The fat extraction was continued in some cases for 18 hours without bringing the results up to those obtained by the Babcock test. The error was then looked for in the steam turbine tester used. A comparison of chemical analysis and hand testers gave practically the same results, while tests of the same milks in nearly all of a number of turbine testers were higher. Bottles which had given results in hand testers agreeing with chemical analysis were placed in turbine testers and whirled for a few minutes, the effect being to increase the reading from 0.1 to 0.2. With rich milk and cream the disagreement was still more marked.

The high results with the turbine testers are considered as fully explained by the expansion of the fat at the high temperatures at which readings are taken. The temperature in the tester was often found to reach 200° F. In the use of such testers it is recommended that before readings are taken the fat be allowed to cool to 140° F. by placing the bottles in water of that temperature, or by leaving the cover off the machine for a few minutes. The only advantage of a very high temperature, as stated, is that the readings may be postponed a little longer. The following disadvantages are pointed out:

"The readings [at high temperatures] are never perfectly clear and distinct, there being always more or less black flocculent matter in or directly below the fat column, or foam on top of it; the bottles are very hot and therefore difficult to handle as taken out of the tester, and owing to the rapid cooling of the bottles when taken out the fat column will sink perceptibly in the neck of the bottles, thus rendering the reading more uncertain."

Dairying, J. FIELDS (*Oklahoma Sta. Rpt. 1899, pp. 81–84*).—Popular notes based on previous publications of the station are given on making butter, feeding dairy cows, and establishing creameries.

Breeding and care of cows, A. SCHMID (*Molk. Ztg., 14 (1900), Nos. 9, pp. 133, 134; 10, pp. 149, 150*).—Various phases of the subject are discussed and variations in the food constitutents of crops grown on different soils and under varying conditions are noted.

Cost of wintering the beef herd, E. R. LLOYD (*Mississippi Sta. Bul. 60, pp. 23–25*).—Data are given relative to the cost of feeding a herd of 25 cows and 1 bull from November 25, 1898, to March 15, 1899. The daily ration consisted of 3¾ lbs. of cotton-seed meal and 9¾ lbs. of cotton-seed hulls, in addition to mixed hay. The cost of feed was $152.92 and labor $8.10. The manure was valued at $87.63, leaving a net cost of $73.39 for the feed and care of the herd for 135 days. Omitting 2 cows, the herd made an average gain from January 10 to February 10 of 12.7 lbs., and from February 10 to March 17 of 2 lbs.

Palm-nut cake and cocoanut cake as feeding stuffs for milch cows, TANCRÉ (*Landw. Wchnbl. Schleswig-Holstein, 50 (1900), No. 9, pp. 145–148*).—The author discusses the character, composition, and relative feeding value and cost of palm-nut cake and cocoanut cake, noting briefly the results of several experiments. Palm-nut cake is considered an excellent feeding stuff for milch cows when fed not to exceed 4 lbs. daily. At that rate it increases the fat content of the milk and gives the butter a pleasant flavor. When fed in larger quantities the butter becomes hard and tallowy. It is thought especially suited to feeding with roots. Cocoanut cake gives similar results except that its influence upon the hardness of the butter is not so marked.

Milk averages, G. D. MACDOUGALD (*Abs. in British Med. Jour., 1900, No. 2055, p. 1248*).—The author, who is the public analyst for Dundee, has published some curves showing the variations in the monthly average composition of 12,069 samples of milk examined from July, 1897, to February, 1900. The average for all the samples was 12.50 per cent of total solids, 3.82 of fat, and 8.68 of solids-not-fat. The curves show little regularity in the variation for different months, except that in the months of August and September the solids-not-fat were generally very low.

Variations in the quality of milk, P. DECHAMBRE (*Ind. Lait., 25 (1900), No. 12, pp. 89, 90*).—Differences in the composition of the first and last milk drawn and variations due to gestation, spaying, individuality, breed, etc., are briefly discussed.

Influence of micro-organisms on milk, DUCLAUX (*Ind. Lait., 25 (1900), No. 9, pp. 65, 66*).—The action of certain micro-organisms on the casein of milk is discussed. In one experiment aerobic bacteria increased the soluble casein in the milk from 0.4 to 1.89 per cent. *Tyrothrix tenuis* in milk containing 3.90 per cent of casein rendered 2.57 per cent soluble. In another experiment all the casein in milk which had been subjected to the prolonged action of fungi passed through a porcelain filter.

Testing skim milk, E. H. FARRINGTON (*Hoard's Dairyman, 31 (1900), No. 15, p. 295*).—In testing skim milk by the Babcock method, high speed and a high temperature are considered essential for the best results. A temperature of 200° F. is not thought too high.

Milk production and distribution from the standpoint of public health, J. TEDDIE (*Veterinarian, 73 (1900), No. 865, pp. 26–36*).—A general discussion of the question, with recommendation of systematic inspection of dairy cows, application of tuberculin test, and exclusion of reacting animals.

The manufacture of butter in Canada, G. APPRY (*Ind. Lait., 25 (1900), No. 16, pp. 121, 122*).—Brief popular notes on methods.

Seasonable notes on cheese making, J. A. RUDDICK (*New Zealand Dept. Agr., Dairying Service Leaflet, 1900, No. 14, pp. 3*).—Brief notes on salting and pressing and on defects in cheese due to faulty methods of manufacture.

Faults in manufacture and diseases of cheese, A. POURRIAU (*Ind. Lait., 25 (1900), No. 17, pp. 129, 130*).—Defects in cheese are noted as resulting from the use of tainted milk or from unfavorable conditions during the process of manufacture, and means of prevention are briefly discussed.

Effect of temperature in curing cheese, R. W. STRATTON (*Amer. Cheesemaker, 15 (1900), No. 169, p. 6*).—In experiments conducted at the Ontario Agricultural College in 1899, cheeses from the same curd were cured in three rooms. The temperature of room 1 was kept at 60° by the use of ice. The temperature of room 2 was controlled by subearth ducts and averaged 65°. No control was used in room 3, which had an average temperature during the season of over 69°. The average percentage of shrinkage for 4 weeks of cheese in room 1 was 2.79; in room 2, 3.14, and in room 3, 4.14 per cent. The cheese cured at the lower temperature was decidedly superior in flavor and texture.

Faults of Gruyère cheese, C. MARTIN (*Ind. Lait., 25 (1900), No. 11, pp. 81, 82*).—A fault of this cheese, designated "lainage" and characterized by cracks in the cheese, is described and means of avoiding it are indicated.

The manufacture of condensed milk, HITTCHER (*Molk. Ztg., 14 (1900), No. 7, pp. 98–100; Milch. Ztg., 29 (1900), No. 9, pp. 132–134*).—An historical and descriptive account of the manufacture of condensed milk.

German laws relating to margarin, G. FULL and M. REUTER (*Die deutscher Margarinegesetzgebung, nach dem Reichsgesetz betreffend den Verkehr mit Butter, Käse, Schmalz und deren Ersatzmitteln vom 15 Juni 1897. Berlin: Paul Parey, 1899, pp. 156*).—Laws of some of the States of Germany relative to the manufacture and sale of butter, cheese, lard, and their substitutes, with detailed technical directions for the analysis and testing of each.

VETERINARY SCIENCE AND PRACTICE.

Report of the bacteriologist, C. E. MARSHALL (*Michigan Sta. Rpt. 1898, pp. 135–138*).—This report covers the subjects of tuberculosis, crown gall in peaches, gassy cheese, suspected hog cholera, and cleanliness in milking.

Studies upon the determination of normal temperatures of cattle have been continued. The station has not so far detected any infectiousness in milk taken from cows condemned for tuberculosis, although numerous tests have been made. Studies are being prosecuted to determine the possibility of infection by urine and feces from tuberculous animals, as well as along lines of curative treatment and eradication of tuberculosis from the college herd.

An attempt is being made to discover the cause of crown gall in peaches, and this matter is being studied at Bangor, Mich., where the disease prevails to a considerable extent.

The organism which causes gas production in cheese has been isolated, and further studies will be made upon it.

In an outbreak of supposed hog cholera on the college farm, as well as in similar outbreaks in other parts of the State, it was found impossible to isolate the hog-cholera germ. These outbreaks are believed to be due to local conditions of climate and food.

A study is being made of the effect upon milk of greater cleanliness in the process of milking.

Report of the director of the stock institute, C. J. POUND (*Queensland Dept. Agr. Rpt. 1898–99, pp. 96–115*).—A brief report is made on the work of the institute in furnishing virus for protective inoculation against pleuro-pneumonia. Numerous experiments were conducted in producing immunity against Texas fever. At the Indooroopilly Experiment Station 38 immune steers and heifers are kept for the purpose of furnishing blood for inoculation. Records are kept as to the amount of blood drawn from each animal. In some inoculation experiments a considerable loss was experienced, and the cause of this loss is discussed by the author. A few cases of temporary insusceptibility to Texas fever were found, and in several instances more than one inoculation was necessary. The question of a possible hereditary immunity was studied by means of the following experiment: Three pregnant heifers inoculated at the same time showed a pronounced temperature reaction, but later recovered completely. When the calves from these heifers became yearlings they were inoculated with the blood of recovered animals. All of them developed high fever temperatures. This evidence indicates that immunity to Texas fever is not inherited.

Observations were made for the purpose of determining the duration of immunity, and the results obtained indicate that the duration varies from 1 to 2½ years. It is found that virulent blood from animals in a high state of fever produces serious consequences when injected into healthy animals. Numerous experiments were conducted in reference to dips and dipping methods. The author states that he has found no dipping method which is certain to destroy the ticks in all stages of their existence which does not at the same time affect the animals unfavorably. The use of arsenic in the destruction of ticks is discouraged.

Observations were made on the effects of low temperatures on ticks, during which 300 fully developed female ticks were placed in a glass capsule and kept at a temperature of 29° F. Every 24 hours 40 ticks were removed and kept in the temperature of the room. All ticks which were removed before the fifth day remained alive and laid the usual number of eggs. After 6 days' freezing a number were found dead, and all were destroyed by 7 days' freezing. The entire progeny of 5 ticks, numbering 10,000 larvæ, were placed in a tube and kept at the same temperature as in the previous experiment. All of the larvæ remained alive until the third day. On the fourth about half of them were dead and by the sixth day all had perished.

The author gives a report of investigations of tuberculosis, with notes on the disease in pigs, sheep, goats, and birds. A brief account is given of the results obtained by the tuberculin test, and the author discusses the problem of heredity and acquired susceptibility to tuberculosis.

Brief notes are given on blackleg and on the use of the bacillus of chicken cholera in destroying rabbits and of the bacillus of mouse typhus in the destruction of mice.

Appended to this report an account is given of investigations carried out by J. S. Hunt, Government pathologist. These investigations include experiments to determine how ticks acquire their virulence. The results of these experiments indicate that nonvirulent ticks do not become infected with the organism of Texas fever from the soil, but that the infection of the ticks is always due to their living upon diseased cattle. A brief account is given of the effects of a large number of ticks upon cattle in producing so-called "tick worry." Further experiments were conducted on the question of inherited immunity against Texas fever. The calves of recovered cows gave a high fever reaction when inoculated with the blood of recovered animals, thus furnishing further evidence that immunity is not inherited.

A further investigation was made upon the cause of rickets, and the author concludes that this disease is produced by eating species of Macrozamia.

Annual report of the Board of Cattle Commissioners of Massachusetts, A. PETERS ET AL (*Rpt. Bd. Cattle Com. Massachusetts, 1899, pp. 98*).—This report contains an account of tuberculosis, glanders, rabies, symptomatic anthrax, actinomycosis, infectious mammitis, and swine diseases occurring in the State of Massachusetts. Notes are given on various features of the quarantine and other regulations of the board.

In regard to tuberculosis the authors make the following recommendations: The maintenance of a quarantine against diseased cattle from adjoining States, the annual inspection by local inspectors of the animals in the State, and the testing of entire herds so far as the funds of the board of commissioners will allow.

It is reported that glanders has been unusually prevalent in the State during the past year. Detailed notes are given on the number of suspected horses which have been tested and the number destroyed. Several outbreaks of rabies occurred in different parts of the State during the year. There was an outbreak of symptomatic anthrax in Ashburnham. The legislature added actinomycosis to the list of contagious diseases, and under the law the cattle commission is empowered to kill animals which are suffering from this disease without appraisal or the payment of indemnity. Two cases are reported of actinomycosis in the mammary gland, which were mistaken for tuberculosis until a microscopic examination was made. A few cases of hog cholera were noted, and one supposed outbreak of hog cholera was found to be due to feeding swill from hotels.

Abortion, W. T. LAWRENCE (*County Councils Cumberland, Durham, and Northumberland, Tech. Education, Rpt. 7 (1898), p. 76*).—This disease being somewhat prevalent on the experimental farm, pregnant cows were treated with internal doses of carbolic acid from March 15 to May 20. The daily dose was $\frac{1}{8}$ oz. of carbolic acid mixed with a dessert-spoonful of glycerin and water and fed with moistened bran. Three out of the eight cows thus treated aborted. On June 18 the stables were whitewashed with hot lime and carbolic acid and the floors treated with a strong solution of copper sulphate. On August 9 was begun a treatment of the hind quarters of each pregnant cow with Nocard's solution, and this was continued for two months. Three out of seven cows thus treated aborted.

Another experiment was tried during which the aborted calf and afterbirth were carefully removed, the hind quarters of the cow washed with Nocard's solution, and a quantity of the solution was thrown on the floor around the cow. This process was continued for three months or as long as any discharge continued to appear. Two cows which aborted in one stable, and one in another stable, were treated in this way and no case of abortion has since occurred.

Contribution to the knowledge of actinomycosis, J. BRAULT (*Arch. Parasit., 2 (1899), No. 4, pp. 535–547, figs. 6*).—A case of human actinomycosis, which developed in extensive ulcerations of the arm, is described and illustrated. The ordinary iodin treatment was given, the doses being gradually increased. At the end of 8 weeks, the dose had reached the size of 4 gm. per day. At the beginning of the treatment local injections of iodid of silver were used.

From bacteriological material obtained in this case, the author made numerous cultures, and notes are given upon the behavior of the organism when grown on different culture media. Inoculations were made with pure cultures in the skin, pleura, tongue, and gums of rats, guinea pigs, and rabbits. One guinea pig, which was inoculated in the pleura, died after 8 days. In all the other cases the animals survived and showed no pathological symptoms, although they were carefully reserved for several months. Two cases of intraperitoneal inoculations are recorded in detail. The one case was in a rabbit, the other in a guinea pig. After a period of three months, these animals died with symptoms of general peritonitis. In both cases until within a few days before death, no symptoms of disease could be noticed. Careful *post-mortem* examinations were made on both these animals and all the symptoms of peritonitis were present. The organism in question was found to be present in the purulent material.

Report on an investigation with regard to the value of tuberculin as a test of the presence of tuberculosis in cattle, J. M. YOUNG and J. S. H. WALKER (*Univ. of Aberdeen Dept. Agr., 1899, pp. 18*).—In this article the authors report the results obtained by the use of the tuberculin test upon 240 cattle and a subsequent *post-mortem* examination of all these animals. The animals upon which these observations were made were killed for market use and the authors obtained permission to apply the tuberculin test before they were slaughtered and to conduct a *post-mortem* examination in each case. The *post-mortem* examinations presented clear evidence of tuberculosis in every animal which had reacted to the tuberculin test. It was found also that a considerable number were tuberculous which had not reacted to the tuberculin test. These cases were either in the very earliest stages or in rather advanced stages of tuberculosis. Thirty one and seven-tenths per cent of all animals examined were found to be tuberculous. It was found in this study that tuberculin loses its virulence when kept for any great length of time.

A number of the animals upon which observations were made were heifers two years of age. Of the heifers 16.6 per cent were tuberculous while 54.5 per cent of the cows were tuberculous. The cows were of an average age of 7½ years. Almost 10 per cent of the cows had tuberculous udders and 16 per cent of the tuberculous cows had tuberculosis of the udder. The authors concluded that tuberculosis of the udder occurs more frequently than is generally supposed.

The diagnosis of glanders, A. DEDYULIN (*Arch. Vet. Nauk, St. Petersburg, 29* (*1899*), *No. 12, II, pp. 565–570*).—Brief notes are given on the reliability of the inoculation of guinea pigs, of the examination of the submaxillary glands, the inoculation of cats, and the use of mallein in the diagnosis of glanders. It has been asserted that the blood of glanderous horses always contains the glanders bacillus in the plasma or blood corpuscles, or both.

In order to test this method for diagnosing glanders, the author made a bacteriological investigation of the blood of 15 horses which were suffering from various forms of glanders. All these horses undoubtedly had glanders as was evidenced by clinical symptoms and by reaction to mallein. Some of the horses had been tested with mallein at 4 different times and had reacted on each occasion. Glanders bacillus was not found in the blood. Two of the horses seemed to be more interesting cases than the others, and the author gives a detailed account of the study of the blood from these 2 cases. The first one was a 12-year-old trotting horse with no clinical symptoms of glanders, with a good appetite and good general appearance. The horse had been under observation for 3 years. There had been a nasal discharge, but this had ceased. Mallein injections had been given at 4 different times, and a decided reaction had been manifested each time. A detailed record of the temperature of this and the other case is given. The second case was a large work horse 8 years of age with a pronounced nasal form of glanders.

The statement has been made in connection with the assertion that the glanders bacillus is found in the blood of glanderous horses, that the number of bacilli is much increased during the temperature reaction to the mallein test. In the case of both these horses, therefore, the author examined the blood from the jugular vein at other times and also at the height of the temperature reaction. It was not only subjected to bacteriological examination, but various culture media and also cats were inoculated. No evidence was obtained of glanders bacillus in the blood. The culture media remained sterile and the cats, although kept under observation for 30 days, did not develop cases of glanders.

Disease among horses, L. L. LEWIS (*Oklahoma Sta. Rpt. 1899, pp. 39, 40*).—A disease which was especially prevalent among horses in the western portion of Oklahoma was found to be confined to horses which were feeding upon grama grass (*Bouteloua oligostachya*) in pastures. The seeds of this grass were largely replaced by smut (*Ustilago bouteloua*). Horses which were not allowed to feed in pastures were not affected by the disease. As remedies the author used potassium bromid, chloral, atropine, and cold packs upon the head, as the case required. Most of the cases, however, ran a short course and were incurable. The symptoms and conditions found upon *post-mortem* indicated an inflammation of the brain, bloody serum being found upon the cerebral membranes.

Treatment of diseases by light (*U. S. Consular Rpts., 62 (1900), No. 233, pp. 191 192*).—A brief report on the Finsen Light Institute in Copenhagen and upon the effectiveness of light rays in the destruction of micro-organisms.

Notes on the inoculation of horses for the preparation of antiplague serum, S. N. RANINA (*Veterinarian, 73 (1900), No. 866, pp. 75–81*).—A discussion of the technique of this method, together with notes on experiments with a number of horses. A bibliography of the subject is added to the article.

A short course in special pathology and therapeutics of the internal diseases of the domestic animals, K. M. HOLTZMAN (*Kratkii Kurs chastnoi patologii terapii vnutrennikh bolyeznei domashnikh zhivotnuikh. Kazan, 1900, 2. ed., pt. 1, pp. 97, figs. 13*).—Nine lectures on the various diseases of the heart and blood vessels.

Œstridæ, and their economic importance, A. BERGMAN (*Svensk. Vet. Tidskr., 4 (1899), No. 10, pp. 433–446*).—Biological and economic notes on species of Hypoderma and Gastrophilus affecting domestic animals.

Actinomycosis, D. WULFF (*Berl. Tierärztl. Wchnschr. (1900), No. 2, pp. 13–17*).—A study of the relative frequency of infection by various channels, such as the mouth, respiratory apparatus, alimentary tract, and skin, together with an account of the frequency of the infection of man with actinomycosis and the necessity of meat inspection.

Contagious agalactia, T. MAZHDRAKOV (*Vet. Sbirka, 8 (1899), No. 2, pp. 25-27*).

A comparative study of antianthrax substances in the dog and rabbit, O. BAIL (*Centbl. Bakt. u. Par., 1. Abt., 27 (1900), No. 1, pp. 10-21*).—The author carried on a number of experiments during which it was shown that the behavior of the anthrax bacillus toward cells and sera of the susceptible rabbit differed in a striking manner from its behavior toward the same materials from the more resistant organism of the dog. It would appear from these experiments that the relationship between anthrax bacillus and antipathetic substances is not so simple as has been assumed, and probably the theories of Metschnikoff, Baumgarten, and Buchner can not be maintained without considerable qualification.

Emphysematous anthrax, Z. G. PUKHALSKI (*Arch. Vet. Nauk, St. Petersburg, 29 (1899), No. 12, II, pp. 583-589*).—The author's observations on this disease were begun in 1890. The course of the disease is always uniform. The attack is sudden with development of high fever, swellings on various parts of the body, difficult locomotion, lameness, a fall of the temperature, collapse, and death within 3 days from the beginning of the attack.

A bacteriological study was made of material taken from the swellings. The author believes, as a result of these investigations, that this disease is distinct from ordinary anthrax.

Bovine distemper, C. MCCULLOCH (*Virginia Sta. Bul. 95, pp. 145-151*).—This bulletin contains brief notes on the history, etiology, symptoms, course, pathology, prognosis, and treatment of bovine distemper.

Contagious keratitis, P. BICHEV (*Vet. Sbirka, 7 (1898), No. 10, pp. 227-229*).—A solution of potassic permanganate, 1 to 2 per cent, was found effective as a wash.

Further investigations into the etiology of pleuro-pneumonia, NOCARD ET AL (*Veterinarian, 73 (1900), No. 865, pp. 36-43*).—Experimental investigations with preventive inoculation against this disease.

Rabies in cattle, W. EDDY (*Jour. Comp. Med. and Vet. Arch., 20 (1899), No. 12, pp. 787-790*).—A study of an outbreak of rabies which was traced to the bites of a rabid dog.

Texas fever (*Oklahoma Sta. Rpt. 1899, pp. 74, 75*).—A brief restatement of some of the results which were published in Bulletin 39 of the station (E. S. R., 11, p. 391).

Veterinary work, L. A. MERRILL (*Utah Sta. Rpt. 1899, pp. 29-36, figs. 2*).—Brief notes on the tuberculin test, together with a general account of the use of blackleg vaccine and practical directions for preparing and applying it.

The thermal death point of the tubercle bacilli in milk and some other fluids, T. SMITH (*Jour. Expt. Med., 4 (1899), No. 2, pp. 217-233*).—In these experiments tubercular material of human and bovine origin was used. The results may be stated as follows: The tubercle bacillus in suspension in distilled water, normal salt solution, or bouillon and milk, is destroyed at a temperature of 60° C. in from 15 to 20 minutes. When the tubercle bacillus is suspended in milk, the pellicle which forms during the exposure at 60° C. may contain live bacilli after one hour.

Some measures lessening the infection and spread of tuberculosis, S. C. JONES (*Jour. Tuberculosis, 2 (1900), No. 1, pp. 1-5*).—Recommends the careful inspection of dairy cattle and milk.

Differential clinical diagnosis of pulmonary emphysema with chronic bronchitis and of pulmonary tuberculosis of the second stage in cattle, G. MOUSSU (*Rec. Med. Vet. Paris, 8. ser., 7 (1900), No. 1, pp. 5-12*).—A study of the symptoms by means of which the two diseases may be distinguished.

Differential diagnosis between tuberculosis and swine plague, S. NYSTEDT (*Svensk. Vet. Tidskr., 4 (1899), Nos. 9, pp. 393-403; 10, pp. 430-433*).—The author discusses in a critical manner the literature of this subject and gives in detail the clinical symptoms and *post-mortem* findings in a number of cases of tuberculosis and swine plague in hogs.

Post-mortem of tuberculous guinea pigs (*Agr. Student, 6 (1899), No. 1, p. 10*).—Notes on the *post-mortem* findings in guinea pigs which had been inoculated with material from old encapsuled abscesses of tuberculous cattle.

New treatment for tuberculosis, W. P. ATWELL (*U. S. Consular Rpts., 63 (1900), No. 232, pp. 31–34*).—A brief account of Dr. Mendel's treatment for tuberculosis, which consists in the use of tracheal injections of a solution composed of essence of thyme, essence of eucalyptus, essence of cinnamon, sterilized olive oil, and iodoform.

Prevention of bovine tuberculosis, E. NOCARD (*Rec. Med. Vet. Paris, 8. ser., 7 (1900), No. 1, pp. 21–32*).—A detailed record of numerous tuberculin tests.

Report of the Board of Sheep Commissioners of Montana for 1899, T. C. POWER and C. HEDGES (*Helena, 1900, pp. 23*).—This report contains a statistical statement showing the condition of the sheep in different parts of the State, a statement of the rules for the guidance of deputy sheep inspectors, a copy of the quarantine proclamation regarding sheep scab, and a report by the State veterinarian on foot rot, sheep pox, and tapeworm.

Diarrhea in young pigs, P. V. KREDBA (*České Listy Hospodarské, 7 (1899), No. 8, pp. 293, 294*).—An account of the etiology of the disease, with suggestion of remedies.

Reappearance of glanders after recovery, NOCARD (*Rec. Med. Vet. Paris, 8. ser., 6 (1899), No. 24, pp. 502–508*).—An attack of glanders followed by recovery does not confer immunity to the disease.

State control of glanders in Minnesota, M. H. REYNOLDS (*Jour. Comp. Med. and Vet. Arch., 20 (1899), No. 12, pp. 737–742*).—A statement of the rules of the Minnesota State Board of Health regarding glanders, and a general discussion of the problem involved in the study and control of this disease.

The diagnostic value of argentum Credé in glanders, RODER (*Deut. Tierärztl. Wchnschr., 7 (1899), No. 47, pp. 417–419*).—From a number of experiments with intravenous injections of argentum colloidale, the author concludes that this substance causes a temperature reaction in glanderous horses and also in horses which are suffering from other internal diseases. The use of the Credé silver preparation, however, renders the final diagnosis more easy and certain. A reaction of 2° C. was manifested within 6 hours after injection with the silver preparation.

The reliability of the Strauss method, M. PRETTNER (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 18–19, pp. 563, 564*).—In experiments conducted by the author it was found that the Strauss method for diagnosing glanders from inoculation of guinea pigs with suspected glanderous material was uniformly reliable.

Contagious pleuro-pneumonia of the horse, CADIOT (*Rec. Méd. Vét. Paris, 8. ser., 6 (1899), No. 20, pp. 361–372*).—The author reports a study of this disease by the military veterinarian, Bourgès, who has studied an outbreak of pneumonia which persisted for 7 months. Young horses were much more frequently attacked than older ones, and horses at the age of 5 enjoyed a complete immunity. One attack of the disease confers immunity of long duration.

Antitoxin in the bile of rabid animals, J. LEBELL (*Centbl. Bakt. u. Par., 1. Abt., 26 (1899), No. 20–21, pp. 635–639*).—The results of the author's experiments may be briefly summarized as follows: The bile of rabid animals regularly produced an attenuation of rabies in experimental rabbits. In some cases the rabies virus and rabid bile were mixed before inoculation; in others the rabid bile was injected after inoculation with the virus. The bile of healthy rabbits had no effect in retarding the progress of rabies.

Rabies inoculations for diagnostic purposes, JOHNE (*Ztschr. Tiermed., 2 (1898), No. 5, pp. 349–371*).—Experimental studies in connection with the diagnosis of rabies. Inoculation is considered the only reliable method.

Chicken cholera, W. EBER (*Ztschr. Tiermed., 2 (1898), No 2, pp. 120–124*).—A discussion of the symptoms of the disease.

Canadian chicken cholera, C. H. HIGGINS (*Jour. Comp. Med. and Vet. Arch., 20 (1899), No. 10, pp. 605–611*).—The author investigated an outbreak of a disease among chickens in Montreal. The symptoms and *post-mortem* findings were in general very similar to those of ordinary chicken cholera. The pathogenic organism was isolated and cultures were made upon several nutrient media. The organism seems to be identical with that of European chicken cholera, but different from the one which is already recognized in America. The author enumerates the differences in the biological and pathological characters of the organisms.

The influence of a preliminary exposure to ammonia vapor upon the incubation of hens' eggs, C. FÉRÉ (*Compt. Rend. Soc. Biol., 11. ser., 1 (1899), No. 30, pp. 806–808*).—A number of experiments were conducted to show the effect of ammonia vapor upon the development of hens' eggs. After such an exposure for several hours it was found that the eggs underwent no development. Upon an examination these eggs presented abnormal conditions. The embryonic area no longer maintained its position on the upper surface of the yolk, but had lost its physical properties and was indifferent.

AGRICULTURAL ENGINEERING.

Irrigation in the Rocky Mountain States, J. C. ULRICH (*U. S. Dept. Agr., Office of Experiment Stations Bul. 73, pp. 64, pls. 10*).—"This bulletin is intended to explain the agricultural conditions prevailing and the methods of acquiring and using water for irrigation practiced in that portion of the arid region covered more particularly by the States of Colorado, Wyoming, Utah, Idaho, and Montana, in which the conditions and methods are somewhat similar. . . . The subject is treated in an elementary manner."

The bulletin discusses the following topics: General characteristics of the Rocky Mountain States; how canals and ditches have been built; operation of canals; methods of applying water to the land; character of supply and use of water; how water rights are acquired and maintained; contracts between corporations and irrigators, and cost and conditions of reclamation of land in the arid region. An appendix briefly describes methods of water administration in the Rocky Mountain States, with lists of irrigation officials.

Sewage irrigation, G. W. RAFTER (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 22, pp. 100, pls. 7, figs. 4*).—This is a continuation of paper No. 3 of this series (E. S. R., 9, p. 393). The first paper dealt with the general subject of sewage irrigation and gave the practice abroad. The present paper "is devoted mainly to the discussion of data obtained in this country and in Canada, and of all the plants erected and operated, together with brief notes on the projected plants. There is included an appendix containing a list of publications relating to the subject."

"In the humid region there are sewage-purification plants in operation, actually building, projected, or built and abandoned, distributed by States as follows: Maine, 1; New Hampshire, 2; Massachusetts, 32; Rhode Island, 5; Connecticut, 7; New York, 33; New Jersey, 11; Pennsylvania, 5; Maryland, 1; West Virginia, 1; Louisiana, 1; Texas, 3; Ohio, 11; Michigan, 2; Illinois, 2; Wisconsin, 2; Minnesota, 1; a total of 120 for the humid region. In the subhumid there is 1 in Nebraska. In the arid region Arizona has 1; Colorado, 4; California, 8; Montana, 1; Utah, 1; Wyoming, 1, or a total of 16. There are also 6 plants in the humid portion of the Dominion of Canada.

"The foregoing figures indicate a total for the United States and Canada of 143. About 120 of these plants have been either built or projected in the last ten or twelve years. This total includes, so far as can be learned, all the purification plants of every kind, whether irrigation, intermittent filtration, or combined chemical-purification and filtration and irrigation plants, either actually in operation now or formally projected and in such a state of advancement as probably to be carried out in a few years.[1]

"The intermittent-filtration plants are properly included in a paper on sewage irrigation, because the filtration areas either now are used for raising crops or are likely in the end to be so used. As to the propriety of including the chemical-purification plants, it may be pointed out that this system of purification has been adopted in several towns before all the controlling conditions were taken into account. In one case an eastern town has adopted chemical purification and operated the plant at large expense, in spite of the existence of ideal conditions for irrigation and filtration in the immediate vicinity. It is probable, therefore, that, as soon as the advantages of irrigation and filtration are more fully known, a number of the chemical-purification plants will be changed to either irrigation or filtration, or, without a complete change of plant, the effluents from chemical purification works will be further treated by either irrigation or filtration."

Pumping water for irrigating purposes (*Irrig. Age, 14 (1900), No. 6, pp. 200–206*).

Irrigation by means of artesian wells in Australia, L. Breymann (*Deut. Landw. Presse, 27 (1900), No. 13, p. 137*).—A brief statement of the number and extent of artesian irrigation enterprises in this country.

Water resources of the State of New York, G. W. Rafter (*Water Supply and Irrig. Papers, U. S. Geol. Survey, Nos. 24, 25, pp. 200, pls. 25, figs. 7*).—These papers deal with the physical conditions of river systems of New York, particularly the available water supply, floods, and low water of some of the typical streams; and with water-storage projects and the development of water power and waterways.

Wells of Indiana, F. Leverett (*Water Supply and Irrig. Papers, U. S. Geol. Survey, Nos. 21, pp. 82, pls. 2; 26, pp. 64*).—This is a record of data "collected in connection with glacial investigations as noted in the general discussion of the water resources of Indiana and Ohio, published in Part IV of the Eighteenth Annual Report of the Survey on pp. 419–559." No. 21 gives a detailed discussion of the conditions for obtaining wells in northern Indiana, No. 26 deals with wells of southern Indiana.

Operations at river stations, 1898 (*Water Supply and Irrig. Papers, U. S. Geol. Survey, Nos. 27, 28, pp. 200*).—These bulletins give "descriptions of the river stations maintained during 1898 by the United States Geological Survey, together with tables of the average daily height of water, results of measurements of discharge, and rating tables constructed from the latter and applicable in general for the calendar year." For reports of similar data for 1897 see E. S. R., 11, p. 196.

Water-right problems of the Bighorn Mountains, E. Mead (*Water Supply and Irrig. Papers, U. S. Geol. Survey, No. 23, pp. 62, pls. 7, figs. 8*).—"This paper calls particular attention to the complications arising in the distribution of water as a result of the haphazard construction of small irrigation ditches. The problems encountered in this region are typical of those which are to be met in nearly every State of the West, or which will be met in the near future. The difficulties found in the area described are accentuated by the diversion of water from one stream across divides into other natural drainage lines, thus connecting and greatly complicating the water-rights of one individual with those of others."

The draft of broad and narrow tired wagons, H. J. Waters (*Pennsylvania Dept. Agr. Rpt. 1898, pp. 519–532*).—An article based on investigations at the Missouri Station reported elsewhere (E. S. R., 9, p. 997).

The improvement of country roads, W. J Roberts (*Washington Sta. Bul. 39, pp. 33, figs. 22*).—A general discussion of this subject, especially as applied to Washington conditions.

---

[1] These statistics were prepared in September, 1897. There have been a few additions since that date.

Principles of construction and maintenance of country roads, F. H. King (*Wisconsin Sta. Bul. 79, pp. 48, figs. 28*).—A general discussion of this subject as illustrated mainly in the construction of a section of a model road near Menomonee, Wis., under the supervision of a special agent of the Office of Road Inquiry of this Department.

STATISTICS—MISCELLANEOUS.

Eleventh Annual Report of Michigan Station, 1898 (*Michigan Sta. Rpt. 1898, pp. 4, 5, 113–602*).—This includes the organization list of the station; a financial statement for the fiscal year ended June 30, 1898; a report of the director on the publications, personnel, and work of the station; reports of the agriculturist, horticulturist, chemist, bacteriologist, and apiarist noted elsewhere, and reprints of Bulletins 145–160 of the station issued during the year. Following are the subjects of the bulletins: Commercial fertilizers (E. S. R., 9, p. 938); bacteria and the dairy (E. S. R., 9, p. 990); pasteurization of milk (E. S. R., 9, p. 986); strawberries (E. S. R., 9, p. 1053); feeding dairy cows (E. S. R., 9, p. 1081); sugar beets in Michigan in 1897 (E. S. R., 9, p. 1045); raspberries, blackberries, and grapes (E. S. R., 10, p. 48); report of South Haven Substation (E. S. R., 10, p. 49); vegetable tests of 1897 (E. S. R., 10, p. 47); some experiments in corn raising (E. S. R., 10, p. 136); spraying calendar for 1898 (E. S. R., 10, p. 470); legislation relating to insects and diseases of fruit trees, and preliminary report of the State inspector of nurseries and orchards (E. S. R., 10, p. 470); hog cholera (E. S. R., 10, p. 596); some experiments with poultry (E. S. R., 10, p. 580); a study of normal temperature and the tuberculin test (E. S. R., 10, p. 692); some insects of the year 1897 (E. S. R., 10, p. 766).

Annual Report of Missouri Station, 1898 (*Missouri Sta. Rpt. 1898, pp. XV+163*).—This contains the organization list of the station, a financial statement for the fiscal year ended June 30, 1898, a detailed review of station work by the director, miscellaneous articles noted elsewhere, list of college and station bulletins, and reprints of Bulletins 40–43 of the station on the following subjects: The sugar beet (E. S. R., 9, p. 944), the San José scale in Missouri (E. S. R., 10, p. 566), the fringed-winged apple-bud moth (E. S. R., 10, p. 564), winter forcing of asparagus in the open field (E. S. R., 10, p. 548).

Fifth Annual Report of Montana Station, 1898 (*Montana Sta. Bul. 20, pp. 91–124*).—This contains the organization list of the station and reports of the treasurer, director, horticulturist, botanist, biologist, chemist, and agriculturist, parts of which are noted elsewhere. Included in the several reports are brief notes on farm improvements, the new greenhouse and steam-heating plant, farmers' institutes, and on plat experiments; lists of exchanges and of bulletins issued; and brief summaries of results obtained during the year.

Biennial Report of North Carolina Station, 1897 and 1898 (*North Carolina Sta. Rpt. 1897 and 1898, pp. 78*).—This covers the work of the station for the two years ended December 31, 1898, and includes a discussion of the relation of the station to the State and National Government, an outline of the history and the organization list of the station, a summary of the publications issued during 1897 and 1898, a brief review of the different lines of station work, and a list of acknowledgments. Departmental reports giving a more detailed account of work in agriculture, chemistry, horticulture, botany, entomology, veterinary science, and fertilizer control are appended.

Twenty-second Annual Report of North Carolina Station, 1899 (*North Carolina Sta. Rpt. 1899, pp. LII+462*).—This is in part reprinted with changes from the Biennial Report of the Station for 1897 and 1898, noted above. It includes in addition the text of the Hatch Act, a summary of publications issued during the year, a financial statement for the fiscal year ended June 30, 1899, and reprints of Bulletins 152–169 of the station on the following subjects: Poultry notes (E. S. R., 10, p. 1087), vinegar adulteration and the extent to which it exists in the samples for sale in North

Carolina (E. S. R., 10, p. 1077), the adulteration of coffee and tea (E. S. R., 10, p. [illegible]), baking powders on sale in North Carolina (E. S. R., 11, p. 278), the adulteration of flour (E. S. R., 11, p. 278), mineraline (E. S. R., 11, p. 278), the fertilizer control for 1896 (E. S. R., 11, p. 229), horticultural experiments at Southern Pines, 1896 (E. S. R., 11, p. 341), digestion experiments (E. S. R., 11, p. 276), drinking water (E. S. R., 11, p. 326), farming in North Carolina (E. S. R., 11, p. 497), rational stock feeding (E. S. R., 11, p. 483), the flora of North Carolina (E. S. R., 11, p. 909), preservatives in canned foods offered for sale in North Carolina (E. S. R., 11, p. 960), butter (E. S. R., 11, p. 984), poultry experiments (see p. 1073), field and forage experiments (see p. 1032), feeding experiments and milk records (see p. 1078).

Annual Report of Oklahoma Station, 1899 (*Oklahoma Sta. Rpt. 1899, pp. 7-96*).—The director's report gives the organization list of the station and reviews the different lines of station work during the year. A financial statement for the fiscal year ended June 30, 1899, and a subject list of station bulletins are given. The report also contains several articles, abstracts of which are given elsewhere, and an extended summary of the results of the more important work done since the establishment of the station.

Annual Report of South Carolina Station, 1898 (*South Carolina Sta. Rpt. 1898, pp. 37*).—This includes the organization list of the station, a financial statement for the fiscal year ended June 30, 1898, a brief report by the vice-director, lists of acknowledgments and station publications, and departmental reports reviewing the different lines of investigation and giving an account of work noted elsewhere.

Eleventh Annual Report of Texas Station, 1899 (*Texas Sta. Rpt. 1899, pp. 55-90*).—The director's report contains a review of station publications issued during the year, and a discussion of farmers' organizations, the organization and equipment of the station, distribution of station funds, and the general work of the station. Resolutions of the Texas Farmers' Congress and the Texas Live Stock Association relating to the needs and work of the stations and substations are given. Reports of the chemist, veterinarian, horticulturist, and agriculturist outline the work in their respective departments. The report of the agriculturist contains in addition conclusions from experiments with corn, reprinted from Bulletin 49 of the station (E. S. R., 11, p. 233). The organization list of the station, a financial statement for the fiscal year ended June 30, 1899, and a subject list of station publications are also included in the report.

Tenth Annual Report of Utah Station, 1899 (*Utah Sta. Rpt. 1899, pp. XLV, pls. 2, fig. 1*).—This contains a report of the director, on the staff, buildings and equipment, publications, and lines of investigation; a subject list of all the bulletins issued by the station; departmental reports reviewing at some length the different lines of station work, and noting briefly methods and results in some cases; a financial statement for the fiscal year ended June 30, 1899; list of periodicals received by the station library; and an index to the report and the bulletins published during the year.

Ninth Annual Report of Wyoming Station, 1899 (*Wyoming Sta. Rpt. 1899, pp. 41-65*).—These pages include notes on the origin and purpose of the station, a brief summary of bulletins issued during the year, an outline plan of station work, a financial statement for the fiscal year ended June 30, 1899, and reports of the director, agriculturist and horticulturist, botanist, chemist, geologist, and meteorologist and physicist reviewing the different lines of station work. Several articles noted elsewhere and reprints of Bulletins 38-40 of the station and Index Bulletin B are appended to the report proper. Bulletin B is an index to Bulletins 27-37 of the station, and Bulletins 38-40 deal with the following subjects: Cultivated shade and forest trees (E. S. R., 10, p. 965), alkali studies, II (E. S. R., 10, p. 1025), the trees of Wyoming and how to know them (E. S. R., 11, p. 53).

NOTES.

California University and Station.—A. P. Hayne, viticulturist of the station, has resigned and accepted a position with a commercial company in Manila. Le Roy Anderson, of Cornell University, has been appointed assistant in charge of dairy husbandry. Carrol Fowler, a graduate of the university, will have charge of the entomological work during the present year, C. W. Woodworth having been granted a year's leave of absence. S. N. Andrews, of Pomona, has been appointed patron of the Southern California Substation in place of C. F. Loop, deceased. A. W. Foster, president of the California Northwestern Railroad, has been made a regent of the university in place of A. S. Hallidie, deceased.

Illinois University and Station.—P. G. Holden, agronomist in the university and station, has resigned to accept a position as field agriculturist for a sugar refining company at Pekin, Ill. C. G Hopkins, chemist to the station, will also have charge of the work of Professor Holden. Professor Hopkins has been spending the past year in study and travel in Europe, but will return in September. W. J. Fraser, assistant in dairying, is now in Europe studying the dairy interests of the more important dairy countries. G. P. Clinton, botanist of the station, has been granted leave of absence to spend the coming year in study at Harvard University. The station departments, with the exception of botany, will occupy quarters in the new agricultural building, the wings of which will be completed in September.

Purdue University.—W. E. Stone, Ph. D., professor of chemistry and vice-president of the university, has been elected president.

Kansas College and Station.—The agricultural department is now located in its new building, which is designed to accommodate that department in respect to class rooms and room for instruction in cheese making and butter making. The machinery for this work is not yet installed. The chemical laboratory was totally destroyed by fire originating in the dark room May 31, 1900. The records of the director's office of the station, the greater portion of the library and office furniture, and considerable apparatus were saved. Some of the samples for analysis in connection with digestion experiments were lost. Several hundred samples of corn which were in process of analysis in connection with work in seed breeding were saved. The fine collection of minerals and rocks, while largely removed from the building, was so badly damaged from the rough handling as to be of very slight value.

Maine Station.—At the June meeting of the board of trustees the following changes in the station staff were made: The resignation of A J Patten, assistant chemist, was accepted; C. D. Holley, B. S., University of Maine, 1900, was appointed assistant chemist; Perley Spaulding, B. S., University of Vermont, 1900, assistant in horticulture, beginning October 1, 1900; Gilman A. Drew, Ph. D., of Johns Hopkins University, entomologist, to date from September 1, 1900, *vice* F. L. Harvey, deceased. J. A. Roberts, of Norway, has been appointed a member of the board of control in place of Arthur L. Moore, whose term has expired.

Montana College and Station.—S. M. Emery, director and horticulturist, has resigned, and S. Fortier, irrigation engineer, has been elected director.

Oklahoma Station.—At a recent meeting of the board of regents E. E. Bogue, botanist and entomologist of the station, was granted a year's leave of absence for the purpose of studying certain plant diseases that have been engaging the attention of the station during the past year. E. M. Wilcox will be in charge of his department during the coming year.

Oregon Station.—B. G. Leedy, of Tigardville, has been elected master of the State grange, and thereby becomes *ex officio* member of the board of regents in place of W. M. Hilleary; and John T. Olwell, of Central Point, has been elected a member of the board in place of B. S. Pague.

South Carolina College and Station.—C. C. Newman has been elected horticulturist in the college and station.

Utah College and Station.—J. W. Kerr, for several years past president of Brigham Young College at Logan, has been elected president of the agricultural college, to succeed J. M. Tanner, resigned. The resignation of Luther Foster as director and agriculturist has also been accepted, and J. A. Widtsoe, formerly chemist, has been elected director.

Virginia College and Station.—John T. Brown, of Brierfield, has been elected rector of the board of visitors of the college and chairman of the board of control of the station in place of C. E. Vawter, resigned. W. A. Hill, of South Boston, has been appointed a member of the board of visitors. Contracts have been awarded for a large pig barn, designed for experimental work, and for a building for farm machinery, shops, etc.

Washington Station.—J. A. Balmer, horticulturist, has retired from the station to engage in commercial horticulture.

Wyoming Station.—B. C. Buffum, agriculturist, horticulturist, and vice-director, has resigned to accept the position of agriculturist in the Colorado college and station. Luther Foster has been elected to succeed him.

Appropriations for the U. S. Department of Agriculture.—The Congressional act making appropriations for the Department of Agriculture for the fiscal year ending June 30, 1901, shows an increase of nearly $300,000 over the appropriations for the preceding year. The total amount is $4,023,500, of which $720,000 is for the experiment stations in 48 States and Territories, and $10,000 for the purpose of commencing the necessary improvements for the establishment and maintenance of a general experimental farm and agricultural station on the Arlington estate, opposite Washington.

The largest increases in the appropriations are for the Bureau of Animal Industry, Weather Bureau, and the Divisions of Forestry and Seeds. The appropriation for the Bureau of Animal Industry is $1,078,830, an increase of $46,800. The appropriation for animal quarantine stations is increased from $12,000 to $50,000. The total appropriation for the Weather Bureau is $1,058,320, an increase of $35,838. The work of the Bureau is to be extended to the Hawaiian Islands. The Division of Forestry receives $80,000, an increase of $40,000, $5,000 of which may be used to investigate forest conditions in the Southern Appalachian Mountain regions of western North Carolina and adjacent States. The appropriation for the Division of Seeds is increased from $130,000 to $170,000. The increased appropriation for the purchase of seed is due in a large measure to a petition of some 225 Members of the House of Representatives.

The appropriation for the Office of Experiment Stations is $33,000, and the special investigations in charge of this Office are provided for as follows: Nutrition of man, $17,500, an increase of $2,500; irrigation investigation, $50,000, an increase of $15,000; $12,000 for the stations in Alaska; $10,000 for a new station in Hawaii; and $5,000 for investigating the agricultural resources and capabilities of Porto Rico, with reference to the establishment of stations there.

The scope of the work of the Division of Chemistry has been somewhat enlarged, and its appropriation increased by $1,000, being now $35,000.

The appropriation for the Division of Agrostology is increased $5,000, making a total of $25,100. The Division of Entomology receives $33,200, an increase of $2,500. Special investigations are ordered on "ravages of the codling moth, with a view to ascertaining the best methods for its extermination." The sum of $34,500 is appropriated for the Division of Vegetable Physiology and Pathology. The policy of Secretary Wilson in employing graduates of agricultural colleges as scientific aids has received the indorsement of Congress by an express provision for the employment in this Division of such aids. Of the $31,300 appropriated for the Division of Soils, $10,000 may be used "for the purpose of demonstrating the practical value of underdrainage and other methods of reclaiming alkali lands." The appropriation for this Division is $5,000 greater than last year.

The fund for investigations as to the adaptability of the South for profitable tea culture is increased from $1,000 to $5,000.

The fund provided for the Division of Publications is $130,020, an increase of $28,360. The amount set aside for the printing of Farmers' Bulletins is $22,500 greater than last year. Four-fifths of the Farmers' Bulletins are to be sent out by members of Congress instead of two-thirds as formerly.

Other items of the appropriation act are as follows: Biological Survey, $30,300, an increase of $2,740; Division of Botany, $43,080, an increase of $14,280; Division of Pomology, $18,400; Public Road Inquiry, $14,000, an increase of $6,000; Division of Statistics, $146,160; Library, $14,000; Museum, $2,260.

MEETING OF THE SOCIETY FOR THE PROMOTION OF AGRICULTURAL SCIENCE.—The twentieth annual meeting of the Society for the Promotion of Agricultural Science was held at Columbia University, New York, Friday and Saturday, June 22 and 23, 1900, in connection with the forty-ninth meeting of the American Association for the Advancement of Science. Dr. W. J. Beal, of Michigan, presided. A joint session with the Association of Economic Entomologists was held Saturday morning, June 23.

The papers presented included Presidential address (delivered in the joint session) and A syllabus for a course on grasses and other forage plants, W. J. Beal; The course of the hyphal filaments of Tilletia in the body of the wheat plant—a correction of an error, H. L. Bolley; Preliminary studies in soil bacteriology, F. D. Chester; Egyptian agricultural institutions, D. G. Fairchild; Development of forestry during the past twenty-five years, B. E. Fernow; Twenty years of progress in plant pathology, B. T. Galloway; Subarctic agriculture, C. C. Georgeson; Experiments in the apiary, C. P. Gillette; Seven years of field experiments with bush beans, B. D. Halsted; The progress in economic entomology during the nineteenth century, L. O. Howard; Some new facts regarding the destructive green-pea louse, with methods for its suppression and control, W. G. Johnson; Humus and soil fertility, E. F Ladd; The development of tomato hybrids, W. M. Munson; Syllabus of a course in the study of cryptograms and The weedy plants of Iowa, L. H. Pammel; Agricultural instruction by the University extension methods, I. P. Roberts; Experiments in liming, W. Frear; Influence of wheat farming upon the fertility of the soil, H. Snyder; The uses and abuses of fertilizer formulæ, S. M. Tracy; Plant breeding, W. W. Tracy; The botanic garden as an aid to agriculture, W. Trelease; How to teach agricultural chemistry to best combine the science of chemistry with the application of it to the affairs of farm life, E. B. Voorhees; Influence of meteorological conditions on the Hessian fly, F. M. Webster; A few points on how to make agricultural chemistry applicable to farm life, J. B. Weems; Formation of sodium carbonate or black alkali by saltbushes and Mutual solubilities of certain pairs of electrolytes in concentrated solutions, F. K. Cameron and F. D. Gardner; and Notes on the comparative hardiness and phenology of some southern and northern trees of the same kind, J. C. Whitten.

The officers elected for the ensuing year are W. J. Beal, Michigan, president; F. M. Webster, Ohio, secretary; and B. D. Halsted, New Jersey, additional member of executive committee.

MEETING OF THE ASSOCIATION OF ECONOMIC ENTOMOLOGISTS.—The twelfth annual meeting of the Association of Economic Entomologists was held at Columbia University, New York, Friday and Saturday, June 22 and 23, 1900, in connection with the forty-ninth annual meeting of the American Association for the Advancement of Science. In the absence of the president (L. Bruner) C. P. Gillette presided. The following papers were presented: Effects of spring application of insecticides, E. P. Felt; Notes on the Marguerite fly, H. T. Fernald; Notes from Colorado, C. P. Gillette; Present condition of the Blastophaga introduction experiment in California, on an introduced parasite of Ceroplastes, and on *Pentilia misella*, L. O. Howard; Notes on insects of economic importance for 1900, and The economic value of certain parasites, W. G. Johnson; The distribution of the brown-tail moth, A. H. Kirkland; Notes on *Diabrotica 12-punctata*, A. L. Quaintance; Hydrocyanic gas on low-growing plants, E. D. Sanderson; Meteorological influences on the development of the Hessian fly, and Insects of the year in Ohio, F. M. Webster; Notes on certain animal parasites, C. P. Lounsbury; Relations of *Pimpla conquisitor* to *Clisiocampa americana*, and an egg parasite of *Vanessa antiopa*, C. M. Weed; Notes from Canada, J. Fletcher; and Notes from California, C. W. Woodworth. For entomological papers presented in a joint session of this association and the Society for the Promotion of Agricultural Science see page 1099.

Officers for the ensuing year were elected as follows: President, C. P. Gillette, of Colorado; first vice-president, A. D. Hopkins, of West Virginia; second-vice president, E. P. Felt, of New York; secretary, A. L. Quaintance, of Georgia. The president, the first vice-president, and the secretary were constituted a committee to pass upon and record common names of insects to be hereafter proposed.

MEETING OF THE AMERICAN CHEMICAL SOCIETY.—The twenty-first general meeting of the American Chemical Society, in affiliation with the chemical section (C) of the American Association for the Advancement of Science, was held at Columbia University and the Chemists' Club, New York, June 25–30, 1900. Addresses were delivered by C. F. McKenna, chairman New York section American Chemical Society; W. McMurtrie, president of the society; and J L. Howe, vice-president Section C, American Association for the Advancement of Science, and some fifty papers were presented Those of especial interest from an agricultural standpoint were: The principal body to which the odor of jonquil is due, T. C. Stearns; The detection of coal-tar dyes in food products, A. L. Winton; Estimation of fat in sweetened condensed milk, J F. Geisler; Some analyses of milk and cream with reference to the condition of fat globules, H. C. Sherman; The action of various preservatives upon cider, E. H. S. Bailey; The toxic action of solutions of acid sodium salts on *Lupinus albus*, L. Kahlenberg and R. M. Austin; Investigations as to the nature of corn oils, H. T. Vulte and Harriet W. Gibson; Some results of experiments with the respiration calorimeter, W. O. Atwater; Notes on the determination of the spontaneous combustion of oils when mixed with wool waste, L. P. Kinnicut and H. W. Haynes; Application of chemical methods to the testing of wheat and flour, H. Snyder; Note on the determination of phosphorus as phospho-molybdic anhydrid, H. C. Sherman and H. S. J. Hyde; The adulteration and methods of analysis of the arsenical insecticides, J. K. Haywood, The composition and analysis of London purple, J. K. Haywood; New methods for the separation of some constituents of ossein, W. J. Gies; and Notes on the constituents of ligament and tendon, W. J. Gies.

MEETING OF THE AMERICAN FORESTRY ASSOCIATION.—The American Forestry Association, in affiliation with the American Association for the Advancement of Science, held meetings at Columbia University, New York, Monday and Tuesday, June 25 and 26, 1900. Addresses were delivered by the Hon. Warren Higley and by the Secretary of Agriculture, Hon. James Wilson, who presided, and a list of some 25 papers on various phases of forestry were presented.

EXPERIMENT STATION RECORD.

VOL. XI. No. 12.

The present number completes the eleventh volume of the Experiment Station Record, and is devoted as usual to the index of the volume. The labor incident to preparing an index of nearly 12,000 entries and putting it through the press is responsible for the delay in issuing it after the completion of the rest of the volume.

The present volume contains 868 pages of abstracts, representing 74,981 pages in the original publications. In addition to these abstracts the volume contains the titles of 2,247 articles, mostly foreign, which are briefly noted, but not abstracted. There are also 15 editorials, occupying 30 pages; 5 special articles, occupying 48 pages, and 129 station and miscellaneous notes, occupying 18 pages.

The review of literature relating to veterinary science has been made much more comprehensive than in previous volumes. The systematic abstracting of publications in the Dutch language has been added, and arrangement has been made for abstracting the agricultural literature in the Hungarian language, which contains much of interest and value.

With the pressure of matter it has been necessary to put more of the abstracts in brevier type than was formerly the case, in order to keep within bounds, and also to omit many of the details which were formerly included. This calls for closer discrimination on the part of the abstractors, and while it necessarily makes the Record more technical in its nature, it will make it more strictly a record of progress in agricultural science.

As the number of volumes of the Record increases the set becomes a more valuable compendium of recent literature on agricultural science and more useful as a means of getting together the literature on a given subject. To facilitate its use, the preparation of a combined index has been undertaken, to cover probably the first twelve volumes of the Record. Work on this combined index is well under way, but the labor involved is very large, and it can probably not be finished before the completion of Volume XII. Such an index will necessarily be less detailed than the index to the individual volumes, and will be made on a somewhat different plan in order to keep it within reasonable size. This can be done, however, without impairing its usefulness.

INDEX OF NAMES.

INDEX OF SUBJECTS.

Page.
Aberia caffra, notes 454
Abortion, epizootic, treatment 289
in cows, notes 696, 995
treatment 88, 192, 289, 495, 1088
N. J 791
sheep, causes and extent of occurrence, N. J 792
incubation period 696
types 92
Acacia cunninghami, notes 220
delibrata, notes 220
penninervis, notes 220
Acacias as forage plants 220
Acclimation fever. (*See* Texas fever.)
Acclimatization of plants 1015
Acetone, occurrence in plants 121
Acid fermentation, relation to butter flavor and aroma, Iowa 388
gases, effect on plants 710
phosphate. (*See* Superphosphate)
solutions, effect on phosphates in soil. 131
Acidimetry, notes 813
Aconitum in North America 709
Acorns, destruction by *Gastropacha quercus* 371
Acrididæ of New Zealand, notes 766
remedies 658
Acridium peregrinum, notes 1063
Acrolein as a germicide 998
Actinomyces, development 893
group and bacteria 494
morphology 393
Actinomyces farcinicus, notes 795
Actinomycosis, frequency of infection by various channels 1090
in Massachusetts, notes 1087
Spain, notes 288
inoculation experiments 1088
notes 91, 285, 995
Kans 498
transmission to man 288, 898
treatment 193, 995
Actinomycosis musculorum suis, notes 288
Æcidia on Umbelliferæ 167, 949
Aeration of the soil 526
Aerial observations, U. S. D. A 127, 621
roots, functions 710
Æthusa minor poisonous to cattle 796
After ripening of small grains 1054
Agalactia, contagious 1091
Agaricus melleus, notes 469
parasitism 516
mucidus, notes 516
velutipes, biology 28

Page.
Agaricus, renamed Psalliota 709
Agave sisalana, notes 443
Agelastica, estivation 656
Agglutinins, relation to lysins in anthrax 494
specific, in bacterial cultures 493
Agricultural—
and plant chemistry 617
Association of Portugal, proceedings. 296
bacteriological laboratory in Russia, report 393
climatology station at Juvisy 821
colleges and experiment stations in the United States, U. S. D. A 98
in the United States, types, U S. D. A. 498
mission 599
statistics for 1899 801
conditions in the Russian Baltic Provinces 296
cooperative societies in Belgium 442
department and experiment stations in Jamaica 808
for the West Indies 101
of Norway, report 799
Sweden, report 197
United States, relation to Weather Bureau, U. S. D. A 126
education, development 999
U. S. D. A 397
in Belgium 498
foreign countries 599
France 599
Ireland 599
rural schools 898
experiment stations. (*See* Experiment stations.)
implements, tests 97
Ind 335
Mich 96
imports and exports, U. S. D. A 296
Institute of Moscow, report 296
institutions in Egypt 1099
investigations in Alaska, U. S. D. A 42
literature of Poland 198
machinery in Denmark 294
materials, analysis methods, treatise 812
meteorology, notes, U. S. D. A 127
treatise 129
organization of Java and Ceylon 999
statistics of Great Britain 296
Students' Association, proceedings, Nebr 296
zoology, text-book 427

Page.
Agriculture and horticulture, school of applied 900
meteorology in the department of Hérault 599
as related to animal physiology 482
soil bacteria, Del. 435
in Alaska, U. S. D. A 98
Denmark 197
Finland, primitive 98
Hawaiian Islands, U. S. D. A. 497
Holland 898
Porto Rico, U. S. D. A 497, 536
Russia 98, 498, 799
Scotland 296
U. S. D. A 999
the South, U. S. D. A 397
instruction at Gembloux 498
methods of teaching, U. S. D. A 98, 799
report of Russian ministry 98
subarctic 1099
text book 599
university extension in 799, 1099
Agrilus anxius, notes 871
bilineatus, notes 764
sinuatus, notes 273
Agriotes obscurus, notes 765
Agromyza æneiventris, notes, U. S. D. A 952
phaseoli, attacking beans 561
n. sp., notes 563
Agrostis vulgaris. (*See* Redtop.)
Agrostology, systematic, recent additions, U. S. D. A 709
Agrotis biconica affecting indigo 1063
exclamationis, remedies 658
infusa, notes 766
messoria, notes, Md 62
saucia, new form 658
segetis affecting indigo 1063
segetum, notes 370, 765
remedies 658
Air currents in thunderstorms, U. S. D. A 620
dynamics, laboratory experiments, U. S. D. A 621
effect on butter 584
flow through rigid porous media 518
iodin content 133
liquid, as a source of power, U. S. D. A 222
methods of examining 482
movements 821
respired, apparatus for measuring 971
temperature at different heights 819
Airol as an antiseptic 797
Alabama Canebrake Station, financial statement 295
College Station, financial statement 697
notes 297, 499
Alaska, agricultural capabilities, studies, U. S. D. A 98
experiments, U. S. D. A 497
botanical survey, U. S. D. A 28
climate, U. S. D. A 31
stations, notes 499
report 43
Albumin, egg, sugar from 23

Page.
Albumin, egg, studies 309, 766
estimation by ammonium citrate 510
hybrid fecundation 1016
Albuminoid bodies of cows' milk 904
total, determination in peptic digestion 971
Albuminoids, determination 418
in urine, determination 23
recent work on 618
Albumoses, determination 311, 813
Alcohol analysis, manual 618
as a protector of protein 576, 672
effect on metabolism 184
muscular work 79
secretion of milk 973
food value 880, 971
U. S. D. A 770
for determining acidity of milk 1007
lactic acid 1006
in milk as affected by distillery malt 284
the vegetable kingdom 1015
manufacture from sugar beets 535
yeasts, genetic relation to molds 125
Alcoholic liquids, determination of fusel oil 313
Aldehyde in leaves 710
Aldehydes as affected by "Sorbose bacteria" 125
Alder, American, notes, Can 855
parasite, notes 467
Aleurodes lactea, notes 66
longicornis, notes 66
tabaci, notes, U. S. D. A 472
Aleurodidæ, notes 476
Alfalfa, analyses 842
Can 617, 662
La 231
Okla 277
Utah 663
as related to bees 266
culture 643
experiments, Colo 339
S. Dak 43
in Kansas 333, 927
digestibility, Can 662
Utah 663
effect on young orchard trees 1048
experiments with Nitragin, Mass. Hatch 516
fall preparation for seeding, Kans 498
feeding value 576
fertilizer experiments 643
for green manuring, Ariz 254, 833
pigs, Kans 377
sheep, Can 662
steers, Utah 663
growing under irrigation 240
hay, digestibility, Kans 381
for pigs, Kans 182, 498
U. S. D. A 397
nutritive value 78
prevention of mold, Kans 333
in eastern Kansas 926
Kansas, Kans 1037
insects affecting 563

Page.
Alfalfa, new species of Cuscuta attacking.. 1057
notes, N. Dak.
pasturage for pigs 1070
sheep, Colo 378
root rot, treatment, Ariz 253
seed of different regions, comparison 156
viability 157
time for cutting, U. S. D. A 599
Turkestan, notes 1037
varieties, Mich 43
Okla 1036
vs. red clover hay for lambs, Can 666
worm, remedies 1064
Algæ as affected by arsenic 1016
certain chemicals 910
effect on greenhouse plants 906
fixation of nitrogen 516
Alinit as a fertilizer 121
bacteria, nitrogen assimilation 1016
bacterium 1016
experiments 26, 711, 1016
in floriculture 424
studies 29, 917, 1016
Alkali, black, formation by saltbushes 1099
effect on forest vegetation 434
plants, U. S. D. A 397
seed germination, Utah 459
Wyo 1052
salts, physiological rôle in plants, U. S. D. A 1008
soils, analyses 823
for sugar beets, U. S. D. A 296
notes, U. S. D. A 133
of Montana 223
plants for, U. S. D. A 397, 423
Alkalimetry, indicators 310
Alkaline chlorids, surface tensions of solutions 112
Alkalis in water, determination 813
Alkaloids in urine, determination 23
rôle in plants 317
vegetable, constitution 619
Allescheria laricis, n sp 556, 1061
Allionia nyctaginea, notes, Nebr 315
Allorhina nitida, notes, U. S. D. A 952
Almond, double flowering, affected by *Monilia fructigena*, Conn. State 757
Alnus viridis, notes, Can 855
Aloes, fungus disease 469
Alpine gardens, plants for 52
plants, production by alternation of temperatures 421
Alternaria brassicæ affecting turnips, Mich. 58
nigrescens affecting muskmelons, Conn. State 755
Alternaria causing muskmelon disease, Mass. Hatch 552
Alum for purification of water 526
Alumina, determination 106, 613
Amanita muscaria, notes 121
pantherina, notes 121
phalloides, notes 121
verna, notes 121

Page.
Amblyomma hebræum, notes.
unipunctata, notes, La 588
unipunctata, notes, Va 173
American Cereal Co. poultry feed, analyses, Me.. 279
meal analyses, Me. 279
Ammonia, effect on incubation of eggs 1093
in fertilizers, determination 506
water, determination 112, 312
oxidation by soil ferments 212
Ammoniacal nitrogen vs. nitric nitrogen 831
Ammonium chlorid solutions, solvent effect on ammonium phosphate precipitate 107
citrate for estimating albumin 510
magnesium phosphate of analysis, constitution 107
phosphomolybdate, precipitation 419
salts, toxic effect 710
sulphate. (*See also* Sulphate of ammonia.)
containing free sulphuric acid 627
fertilizing value 438
Amœba meleagridis, notes, U. S. D. A 985
Ampelopsis, diseases, treatment, N. J 752
Amphicarpæa monoica, notes 817
Amphicerus bicaudatus, notes, U. S. D. A. 366, 952
Amphistomum hepaticum, notes 289
Amygdaleæ, hydrocyanic acid content 320
Anaerobic bacteria as causes of disease 194
studies 288
